It is obviously important that the nature of an apparently powerful immunising agent like the Vi antigen should be determined The antigen is recognisable serologically, but the example of the de acetylated pneumococcus polysaccharide is a warning against the common fallacy of arguing from a serological to an immunological entity. A purified end product of chemical fractionation may be precipitated by an immune serum as effectively as a crude watery extract of the bacterium so treated, but this fact is no guarantee that the precipitated substance has remained unchanged during the process The ultimate isolation of an immunising substance is most safely achieved by rigid tests of all products for actual immunising power This method was adopted by Prof TOPLEY and Prof RAISTRICK and their colleagues in their isolation of the antigens of *Bacterium typhi murium* and has been applied to their study of the Vi antigens of the typhoid bacilli published in our present issue The immunising fraction of *typhi murium* survived tryptic digestion of acetone extracted bacteria, and could be precipitated from the tryptic digests The typhoid antigens are apparently similar, and analysis, on these lines, of a Vi strain and an ordinarily virulent O form of the typhoid bacillus reveal definite and significant differences in the immunising and chemical behaviour between comparable fractions of the two strains The most powerful immunising antigen is derived from the Vi strains, but the O antigens are far from ineffective in this respect, for repeated injections of the O antigen are as effective as two injections of the Vi antigen in protecting the mouse from lethal doses of living typhoid bacilli Though Vi forms are probably the best immunising agents, the O forms hitherto employed in the preparation of vaccines have a definite efficacy of their own

[2] See references given by Topley and others (p 256) of our present issue

Though the results so far obtained are sufficiently clear cut, the exact nature of the antigens remains to be determined. The work is far from easy; one of the chief difficulties lies in the choice of suitable chemical methods of isolation. It is instructive in this respect to compare the methods used for the typhoid bacilli with those used by Dr STAMP and Miss HENDRY for the isolation of immunising fractions of hæmolytic streptococci (see p. 257). The typhoid fractions are polysaccharides linked on to other molecules, whereas the active streptococcal fractions appear to be protein in nature, and the dissimilarity illustrates the laborious and groping methods of analysis that are needed for each fresh bacterium tackled. Both papers raise a point of immediate interest—the isolation of relatively pure stable substances capable of inducing good antibacterial immunity. The ease of manufacture and the effectiveness of streptococcal antitoxin has overshadowed the possible value of antibacterial sera. But in view of the doubts of the efficacy of streptococcal antitoxins expressed, for example, in the report of L. COLEBROOK[2] the problem of attacking the infecting cocci themselves as well as the exotoxins they produce becomes more urgent. The hæmolytic streptococci are divisible by the precipitin reaction of Lancefield into a number of subgroups each antigenically distinct. Dr STAMP and Miss HENDRY, in obtaining effective fractions from a streptococcus belonging to Lancefield's human pathogenic group A and from a cattle pathogenic strain of her group C, have made a beginning of the immunological analysis of this highly complex group.

One more point deserves mention. Successful isolation depends on adequate assay of the products, and here the difficulties are more economic than technical. A dependable estimate of the immunising property of a single fraction uses, if the test is to be adequately controlled, sixty mice. A complete survey of all the fractions from a bacterial analysis may require prohibitive numbers of animals. But without the foundation of the statistically significant results that follow the use of adequate numbers of test animals very little of value can come out of immunological experiments except by happy but scarcely dependable chance.

SIR HENRY WELLCOME'S WILL

PARTICULARS of the will of the late Sir Henry Wellcome were published in September last when the gross value of the estate was declared, but some time must elapse before the exact sum in death duties will be arrived at. Specific bequests were considerable, while in respect of the rest there was an appointment of trustees, the terms of which are set out by them in a letter which appears this week in our columns. The trustees here explain why they have been unable to consider appeals for contributions which have arisen from various research undertakings, received as a natural sequence to the general knowledge concerning the directions in which the bulk of the fortune was to be used.

The letter from the trustees is so detailed and clear as to leave no need for exposition. By the terms of the will the shares of the Wellcome Foundation, the company formed to take over the whole of the business activities of Burroughs Wellcome and Co., became vested in trustees, while provisions have been made for a welfare fund for the benefit of employees of the Foundation, for the payment of certain specified annuities, and for the erection and maintenance of a memorial building to the testator's parents. The Foundation includes the various institutions and museums which were established by Sir Henry Wellcome, who held the whole of the share capital, and this is now vested in the trustees in accordance with the testator's instructions. Subject to the charges mentioned above the remainder of the disposable profits of the Foundation were by the terms of the will to be employed for the maintenance of two funds—the Research Undertaking Charity and the Museum and Library Charity. The scope of these funds is set out in the letter of the trustees, and we have presented to us a concrete conception of the mighty influence which well-directed scientific research can have upon world conditions. Thus the responsibility placed upon the trustees is a truly heavy one, and its discharge will call for great knowledge of the directions which medical progress may take and proportionate judgment in the disposal of large sums of money. The trustees are Mr G. Hudson Lyall and Mr L. C. Bullock, members of a city firm of solicitors, Mr Martin Price, a chartered accountant, Sir Henry Dale, F.R.S., and Prof. T. R. Elliott, F.R.S. The testament imposed upon the trustees an obligation to enter into a covenant not to be engaged in, or in any way to assist in, any business competing with the Burroughs Wellcome company, and the scientific and medical trustees, Sir Henry Dale and Prof. Elliott, might be placed in a difficulty if certain words in the covenant were held to restrict their performance of official or general duties towards medical science, or to imply their particular concern with the business interests of the Wellcome Foundation. Wisely, therefore, legal advice was sought to make clear the position, and appended to the letter of the trustees will be found a copy of an Order obtained from the High Court of Justice dealing with the situation.

The endowment for the benefit of mankind designed and made possible by Sir Henry Wellcome's will is remarkable not only for its generosity but for its foresight. The terms are sufficiently precise to enable the testator's objects to be realised, while those objects contemplate an indefinite development within broadly specified lines.

THE death occurred on Saturday last of Dr. Henry Alexander Osborn, a well known pathologist working in Liverpool. The tragedy occurred through an infection contracted in the course of his work. He was only 43 years of age.

ANNOTATIONS

KING GEORGE V MEMORIAL

ONE evening last week an appeal was broadcast by Lord Dawson of Penn on behalf of the King George National Memorial Fund for the provision of playing fields throughout the country Lord Dawson made a moving reference to the closing scenes of the life of King George V, emphasising his resolute performance of duties during declining health, and his deep concern for his people The object of the Memorial must commend itself to all medical men as being devised for the well being of youth King George, said Lord Dawson, saw clearly that the future prosperity of the country lay with youth, and subscribed to this vision by adding that "as time goes on it will be found that the school which teaches health, the hospital which restores health, and the open spaces which make for health are all part of one great conception" Lord Dawson's appeal was made on the last day of the Odd Shillings and Pence Appeal, but this does not mean that the appeal as a whole is closed, an impression which it is hoped our readers will not allow their patients and friends to remain under Contributions to the fund should be sent to the Lord Mayor of London at the Mansion House

THE TREND OF THERAPEUTICS

IT is notoriously difficult to write contemporary history, yet we are ever striving to assess the value of our own contribution to the story of mankind. Those who try to see present events impartially and in proper perspective are, consciously or unconsciously, making the difficult experiment of transporting themselves into the next century, and viewing the present through the eyes of a future generation Too often, we feel, such adventurers deserve little sympathy, but in medicine their function is obvious and important It is not only interesting, but vital, that growing points should be recognised and nourished. To day we are on the threshold of developments in medicine which may parallel those of surgery during the last seventy five years The recent rapid progress in the field of endocrinology has furnished the occasion for some of the finest chemical work of the century, and the chemists are no longer technicians only, but pioneers The discovery of the constitution of a hormone is a major event, and its successful synthesis hardly less so, but the research worker does not now retire at this stage in favour of the manufacturer and the clinician The hormone may contain two or more well known chemical groupings of elements, and it is important to know which of these is responsible for the characteristic effect More important still is the fact that each of these groupings relates the substance to a whole family of other compounds, natural or synthetic, all containing different modifications of the same nucleus The various relatives of adrenaline, such as ephedrine and benzedrine, and the family of œstrogenic compounds are familiar examples of this Their clinical importance lies in the probability that different members of the series will be found adapted to different circumstances in treatment We use adrenaline in asthma as an emergency measure, but ephedrine for a prolonged effect

We have long been familiar with the same principle in the pharmacology of the nitrites, but much more complicated drugs are now being subjected to the same kind of scrutiny and experiment Our breakfast literature bears witness to the zealous search for the perfect drug, and its chemical name, formidable in its lack of hyphens, means that it is not an accidental discovery, but a carefully thought out product which the manufacturer would have us believe is eugenically perfect Usually he either overrates or underrates our intelligence, but he faithfully mirrors the modern emphasis on the relation between chemical structure and biological activity Why this should coincide with a decline in the importance of pharmacology in the medical curriculum is difficult to understand

On another page are reports by Mr J S Maxwell and Dr Chassar Moir on the clinical trial of carbaminoylcholine Even H G Wells might have paused before predicting a pharmacological substitute for the catheter, yet here we find evidence that, so far as post operative and post partum retention are concerned, such a substitute has been found Sir Henry Dale and Prof Otto Loewi have lately received the Nobel prize for their researches into the physiological importance of acetylcholine in transmitting the effects of nerve impulses The control and innervation of the bladder have had much attention from research workers in recent years, both in this country and in America For many years the family of compounds to which acetylcholine belongs has been the subject of chemical and pharmacological investigation In the trial of carbaminoylcholine in the treatment of retention of urine we have an experiment based on straightforward deduction from facts which have been largely established in the laboratory It is, perhaps, a coincidence that the same series of physiological researches formed the basis of a similar experiment in the trial of Prostigmin for myasthenia gravis, but there can be little doubt that we are destined to become increasingly familiar with such experimentation We are daily amassing more and more precise information about the actions and chemistry of hormones, drugs, vitamins, and other highly potent substances, such as acetylcholine, produced locally in the body Precision of knowledge means precision in treatment, and precision in treatment will do more than many conferences to simplify the medical curriculum

THE CANCER VIRUS

A SINGULARLY clear paper by Dr C Russell Amies from the Lister Institute in the January issue of the *Journal of Pathology and Bacteriology* goes far to confirm and clarify the work of Ledingham and Gye on the particulate nature of the active agent in bird tumours Tumour extracts ground with sand and finally frozen and thawed several times to kill any cells which might survive, contain a heterogeneous collection of particles Moderate centrifugalisation removes most of this debris and leaves the infectivity of the supernatant liquid unimpaired If this liquid is then centrifuged more violently—e g, 12,000 revolutions per minute for 2 hours or 33,000 for half an hour—the whole of the infective agent is thrown to the bottom of the tube and the supernatant fluid is innocuous though it still contains fine particles visible by dark ground illumination That the agent is particulate is not new, but these experiments show that infectivity is associated with particles of a certain size and that when these are emulsified in liquid and tested on fowls they represent the whole of the infectivity of the original extract Microscopically these preparations contain a great number of particles of approximately the same size and of similar optical appearance they are too small to be seen clearly but their appearance would be compatible with their being about 0 1μ in diameter which is in reasonable correspondence with the size determined by Andrewes and Elford by filtration and centrifugalisation. The number of particles in a suspension was not determined but Amies makes the point that it was obviously greatly in excess of the number required on the assumption that one particle could start a tumour—which suggests that none of these very small bodies can do anything unless there are many of them the unit of action may well be a crowd rather than an individual. If these particles are not the actual tumour virus the tumour exciting property evidently resides in and cannot be dissociated from them The suspensions are agglutinated by the serum of most fowls carrying tumours and of some normal fowls though not by the serum of chickens, a result which by itself might be due to the particles being the result rather than the cause of the disease they show however they can hardly be normal fowl tissue Agglutinating sera generally also have the power of neutralising the infectivity of suspensions if the two are allowed to react together for a few hours before being inoculated into the test hen Suspensions are not agglutinated by antifowl serum made by dosing rabbits with fowl blood which is the best available evidence that they do not contain fowl protein But in a series of striking experiments previously made in a cruder way by Gye and Purdy Dr Amies shows that this antifowl serum will neutralise the infectivity of his purified emulsions and draws the natural deduction that the tumour agent contains something which is normally present in fowl tissue This is difficult to reconcile with the view that the tumour virus is an independent organism unless it is a parasite which in some curious way takes on a stamp from its host

TRANSURETHRAL OPERATIONS

DURING the past five years the great value of transurethral operations for the relief of various disorders of the bladder urethra and prostate has become apparent for they can now be employed in many cases in which open surgical operations were formerly required Elderly patients who because of the risk involved declined to submit to other types of operation are now reporting to the urologist for the transurethral operation and are being relieved of symptoms with minimal risk. Although resection of the prostate gland for enlargment is by far the commonest of these procedures, it is by no means the only one. Extensive tumours of the bladder that previously called for open excision can be tackled with a McCarthy resectotome the bulk of the growth being rapidly removed with a cutting current and the pedicle or base afterwards thoroughly destroyed by electrocoagulation In a review of the subject Dr G J Thompson of the Mayo Clinic claims [1] also that the scope of litholapaxy as opposed to suprapubic removal has been greatly increased In his opinion prostatic enlargement is no contra indication to the use of the lithotrite and he is in the habit of treating both conditions at one sitting crushing the stone and then dealing with the enlargement by means of an electrotome. Other conditions in which the electrotome will be found useful are prostatic calculi prostatitis and prostatic abscesses both *acute* and chronic Even vesical dysfunction due to a *lesion* of the central nervous system may yield to the division of the internal sphincter by means either of a McCarthy instrument or of a Collings s knife For the results of resection for prostatic obstruction Dr Thompson gives very impressive figures Of 1987 patients subjected to transurethral *resection* for either benign or malignant disease of the prostate during the four years 1932–35 only 14 died a mortality *of* 0 7 *per cent*

HISTORY OF BUBONIC PLAGUE IN PARIS

A FAMOUS mystery story had as its plot the disappearance of an Englishwoman during the night after her arrival, in company with her daughter in Paris No trace of her existence could be found next day and her daughter's frantic protests met blank denials—from hotel staff police and finally from the highest *officials*—that she had ever arrived The solution it will be remembered was that the great Exposition of 1900 had just opened that the lady had died of bubonic plague and that news of this must at all costs be suppressed

Allegations of such official suppression if they ever existed outside fiction are effectively answered in an account by Dr E Joltrain [1] of the 138 bacteriologically confirmed cases of plague observed in Paris from 1917 to 1937 The last two years have been happily free and in fact there have been but 6 cases in all in the last ten years The first case—indeed so far as is known the first for almost three hundred years—was in December 1917 Gland puncture of a dying child admitted to the Bretonneau with axillary adenitis gave a microscopical picture typical of plague. No other fact and no other cases were discoverable and the observation remained a bacteriological curiosity until 1920 Then another similar case occurred but this time it was followed not only by full laboratory confirmation but also by the detection of a whole series of other cases all more or less directly in communication and all among rag picker families though in four separate districts These four foci in slum dwellings in Clichy Saint-Ouen Levallois, and Pantin continued to furnish cases throughout 1920 the total for the year being 106 notified 91 confirmed 37 fatal. There were only 3 deaths (6 per cent) among the 52 treated cases in most of which large doses (100–200 c cm) of the Pasteur Institute antiplague serum were given; but among the 39 untreated no less than 34 (87 per cent.) were fatal. By the end of 1920 the plague was beginning to abate and there were only 10 5 and 11 cases bacteriologically confirmed, in 1921 1922 and 1923 respectively Joltrain mentions that in 1920 there were almost as many with even higher mortality in Marseilles; but the history of Marseilles would require a chapter to itself It is sometimes forgotten that Paris too is a seaport and it is probable though the facts can now never be established that the infection was ship borne Joltrain says categorically that in 1917 plague rats escaped at Levallois from a ship bringing coal from England after a previous voyage to India. One may be permitted to doubt so elegant a sequence: in fact, no plague infected ship arrived in Cardiff in 1917 and though more than one arrived in the Thames in that year these were thoroughly fumigated before clearance and no plague rats were found a hore in the Port of London then or since That rat plague existed in Paris during the pre epidemic years of 1918–19 is, however, highly probable It was recalled, when inquiry was made, that dead rats had been found with abnormal frequency, and two of the first persons to get plague in 1920 had actually handled a sick rat and been bitten by its fleas Since then examination of rats for plague infection has been regular in Paris In 1921 7000 were examined by Tanon and Neveu in their special plague laboratory, these yielded 41 positives, in 1924, 2840 rats gave 50 positives, as late as 1933, 2770 rats gave 5 positives, and it is far from certain that rat plague does not still exist

---

[1] *J Amer med. Ass.* 1936 107 1931

[1] *Bull. Acad. Méd. Paris* 1936, 114 631

Little new is to be learnt about the epidemiology of plague from the Paris observations The cycle is as usual rat→flea→man, and infestation of the rats by *Xenopsylla cheopis*, as well as the common rat flea, *Ceratophyllus fasciatus*, is noted by Joltrain The main lesson—and it is one that we in England should not scorn—is that the existence of rat infested slum dwellings in a city is a perpetual invitation to invasion by bubonic plague It is no doubt true, as Indian experience shows, that even when such plague infected slum foci exist, the disease will spread hardly, if at all, from them to quarters of proper sanitary construction But the mysterious penetrations of which rats are capable, even in urban districts so unfavourable to them as the City of London, would create enormous anxiety, nourished, as it would be, by sporadic cases of the dread disease in the most unexpected places, as happened indeed in Paris So no effort should be spared to reduce our rat population to a density low enough to prevent the spread of plague among them Our experience in East Anglia 25 years ago shows that such reduction will, in fact, extinguish a rodent enzoötic, though, it is true, that was under rural conditions, where dispersal of rats was easy Vigilance against introduction remains the best defence and the experience of Paris is a warning of the consequences of its failure

THE APPENDIX IN MEASLES

DISCUSSING appendicitis as a complication of the acute specific diseases, Ronaldson [1] finds that although some French writers attach importance to its supposed relationship to scarlet fever, the experience of several of the large fever hospitals in London shows that the association is rare He records two cases under his own observation, but discovers no demonstrable connexion between the patients' appendicitis and the scarlet fever from which they were convalescing Indeed, he suggests that the appendix, "the abdominal tonsil," seems to enjoy a high degree of immunity from the septic manifestations of the disease The possible association of appendix symptoms with measles is distinctly more interesting, for although suppurative appendicitis is very rare, Ronaldson says that transient pain in the iliac region may be a feature of the first day of the prodromal stage of measles, and surgical aid may thus be sought unnecessarily Wegelin [2] has just recorded three cases in which appendicectomy with uneventful recovery, was performed in children who developed acute appendicitis in the prodromal or earliest eruptive stage of measles, and in view of his remarks about the mildness of the inflammatory changes found on microscopical examination it seems possible that these were all examples of the appendicular colic alluded to by Ronaldson Both authors refer to the histological investigations of the tonsils in early measles carried out independently and almost concurrently by A S Warthin and W Finkeldey in 1931 These workers found characteristic giant cells in the tonsillar tissue and, in 1932, M. Herzberg demonstrated similar giant cells in the mucosa of the appendix removed from measles patients In all of Wegelin's cases identical giant cells were present in the lymphatic tissue of the appendix and in one of them they were found in the neighbouring mesenteric glands also Wegelin thinks that the occurrence of the Warthin Finkeldey giant cells is specific for measles and of diagnostic importance More practical, however, is Ronaldson's advice that appendicular symptoms in young subjects should lead to a search for Koplik's spots, whose discovery may obviate too hasty interference On the other hand Wegelin refers to a case recorded by Hathaway in which a boy in the prodromal stage of measles, infected by his sister, died from perforative appendicitis Histological examination revealed giant cells in the bronchial and retroperitoneal lymphatic glands and in the spleen, but not in the appendix or mesenteric lymphatic glands Unless the patient can be kept under constant observation, as in hospital, most practitioners, having diagnosed measles in a child who also presents symptoms pointing to appendicitis, will want to share their responsibility with a surgical colleague at the earliest moment possible.

EXACT KNOWLEDGE OF OUR COLONIES

"IT would scarcely be an exaggeration to say that the majority of English people of the present day have but the vaguest notions of the extent and resources of the Colonial Empire" Starting from this submission, Major P Granville Edge (lecturer in the division of epidemiology and vital statistics in the London School of Hygiene) in a paper read to the Royal Statistical Society at their meeting on Jan 19th set about the task of giving the statistician, at least, no excuse for his ignorance of the demography of the British Colonial possessions, a task most ably fulfilled These possessions, he said, comprise upwards of fifty distinct governments, have territories extending over an area of more than two million square miles, and a population of over 58 millions, or double the total inhabitants of Canada, Australia, New Zealand, and South Africa Rather more than nine tenths of this area and this population lies within the Tropics, and we have to deal with a "bewildering medley of races, religions, languages, and customs" Using the annual medical and sanitary reports of the different territories Major Edge discussed the rates of birth, death, infant mortality, and sickness which are recorded Such material must be handled with caution, for the difficulties under which medical officers concerned with native races have often to work lead to inevitable imperfections To take one example Major Edge refers to the "bad luck" belief which may cause native parents to omit any reference to the eldest surviving child. A husband with two wives and eight children reports seven offspring, the two wives interrogated about their own offspring report six, each deducting one, interrogated about each other's offspring they give the true number, eight

But such difficulties in the way of census taking and of registration, and the present difficulty—perhaps impossibility—of interpreting some of the figures obtained, must clearly not lead to a counsel of despair The road to accuracy may be long and troublesome but, however slowly it must be followed Only with a knowledge of the numbers and the constitution of a people can the machinery of government function properly and sanitary measures be taken only with a knowledge of vital statistical rates can the effects of such measures be assessed Those on the spot who take interest in these matters and make real attempts to collect the data need all the encouragement that can be given them and not as Dr Balfour Kirk remarked in the discussion following Major Edge's paper the damning with or without faint praise of their efforts by those accustomed to dealing with figures collected under the registration system of a civilised country It is also a serious mistake if the worker in the colonies is deterred from his vital statistical studies by to quote Dr Kirk's words the mathematical smoke screen with which he is faced when he consults the work of the professional statistician.

[2] Wegelin C (1937) *Schweiz med Wschr* 67 1

Much can be done under primitive conditions by simple statistical means by the careful and logical consideration of the figures collected But at present Prof. Greenwood suggested we regard our colonial vital statistics much less seriously than do the Dutch a difference which lies in Major Edge's view in the fact that in many of our possessions we are content to record the ascertained data, while the Dutch are concerned to interpret them—to get below the figures and to relate them to other recorded facts such as environmental conditions As the lecturer has suggested in another place [1] facts are stubborn things and often seem dull, yet they are the seeds of imaginative ideas which the wit of man is often able to transmute into practical realities There is no dearth of problems to solve if the interest is there to solve them Major Edge's paper should do much to arouse that interest and to create a more serious regard for medico statistical work amongst the native races in the British *possessions*

HEATED ETHER VAPOUR

IT has been claimed for a good many years that there is advantage in offering ether vapour to a patient warm rather than cold Shipway's widely used apparatus had this for one of its primary objects. It must be admitted, however that some have always maintained that the advantage is slight and counterbalanced by attendant disadvantages They have said that the vapour whatever its temperature when inhaled reaches blood heat before it enters the pulmonary alveoli and that the only value of warming it is to conserve the small amount of body heat expended in raising the vapour temperature to that of the body Even this gain they believe is more than offset by the increase of sweating associated with inhalation of warm vapour This argument takes no account of the newer possibilities of superheated ether vapour and in the light of Tiegel's observations [2] the question assumes new importance German authorities who have employed this vapour of a temperature much higher than that commonly used here declare that it is less irritating than ordinary ether vapour that it does not produce the same mucous secretion that it gives a prolonged analgesia both before and after true anæsthesia that it is very quickly recovered from and far less often followed by nausea or sickness Obviously these claims if substantiated mark a real advance The necessary apparatus is complicated and it will be of much practical benefit if the comparatively simple instrument used by Dr Garnet King of Los Angeles supplies a vapour of temperature high enough to have the virtues of Tiegel's method. King's Thermanester is we believe now to be obtained in this country and doubtless anæsthetists are trying the new version of warmed ether in order to determine its true value That it should be less irritating to the upper air passage and therefore more easily and comfortably inhaled than cool vapour seems on the face of it highly probable The pumping action of Shipway's apparatus may have impeded this effect during induction.

THE DISTRIBUTION OF STATE-REGISTERED NURSES

EACH year State registered nurses are sent official forms which they have to fill in and return with retention fees if they wish to keep their names on the register This year 72 059 nurses were circularised by the General Nursing Council for England and Wales and for the first time a questionnaire was issued with the forms in order to ascertain the distribution of State-registered nurses through the different branches of the profession Only 4002 less than 6 per cent failed to respond to the questionnaire and these were mostly nurses living abroad of the rest 55 956 were and 12 101 are not in active work. By far the largest group (27 190) are holding hospital appointments 16 381 are private nurses; 5029 are public health nurses (including industrial nurses) 4043 are district nurses and 1646 are taking further training These five groups account for nearly 54 000 women—none of the 24 *occupations* among which the remaining 2000 are distributed includes as many as 300 The very large proportion (approximately half) of State-registered nurses employed in institutions lends force to the plea made by THE LANCET Commission on Nursing for a greater measure of personal freedom for them when they are off duty There are still far too many hospitals in which qualified staff nurses are subjected to much the same restrictions as are appropriate for probationers, and this is certainly one of the factors influencing the shortage of suitable candidates for the profession.

USE OF THE DEVELOPING EGG IN VIRUS RESEARCH

THE inability of viruses to multiply apart from living cells has undoubtedly been one of the chief contributory factors to the difficulty of virus research The isolation of a virus and its maintenance in the laboratory has depended on the use of experimental animals and though the tissue culture technique more particularly in its simplified form devised by H B and M C Maitland [1] has been of great service in the study of viruses it has only replaced the living animal to a very limited extent This unavoidable reliance on the animals carries with it many disadvantages Some viruses causing disease in man such as those of zoster and varicella are apparently unable to infect other animals and so remain largely unstudied others like those of the common cold can only be transmitted to a species of animal which because of its expense must be used sparingly Even where a suitable experimental animal exists all sorts of pitfalls such as the presence of dormant viruses or the occurrence of cross infection exist to entrap the unwary or complicate the task of the experienced worker However the work done during the last four or five years on the suitability of the chorio allantoic membrane of the developing egg for the cultivation and study of viruses indicates a way out of many of these difficulties First used by Rous and Murphy in 1911[2] in the study of fowl tumours, the membrane was found by Goodpasture and Woodruff,[3] some twenty years later, to be admirably adapted to virus work Since then a number of virus workers have made use of this new technique, and of these one of the most successful and enthusiastic has been F M. Burnet While working in this country at the National Institute of Medical Research, and since his return to Australia, Dr Burnet, either alone or in collaboration with others, has published a series of papers indicating the scope of this new method He has now written a very valuable monograph on the subject which is published by the Medical Research Council[4] This report is not just a survey of published work, it contains many new observations and suggestions as to the possibilities of this method It must not be imagined, of course, that the egg membrane is available for use with all animal viruses, some viruses fail entirely to infect the chorio allantoic cells But it is quite surprising on reading this report to find how many viruses can be grown under these conditions It has even been possible by serial passage to adapt the virus of epidemic influenza to the egg membrane, and the possibility of using these undifferentiated cells in the study of viruses which it has been impossible to establish in experimental animals naturally occurs to one Quite apart from this the egg membrane constitutes an ideal "animal" for virus study It is very cheap, and requires the minimum of attention It is free from contaminating bacteria and viruses and cross infections do not occur Further the chorio allantoic membrane provides a beautifully simple tissue in which to study the histological reactions to virus infections There is not the least doubt that this new technique will be extensively adopted in virus research, and those workers contemplating its use will be grateful to Burnet for this lucid monograph.

HOME v RESTAURANT IN RUSSIA

IF people do not get the right food the reason may be that they cannot afford it, or do not choose it, or they may spoil good material before it reaches the table It has been noticed that those who live near the borderline of starvation are often unwilling to listen to advice about the choice and preparation of their meals, and this reluctance must be borne in mind by those who hold that if our population is to be better fed the steps most needful are educational rather than economic In a valuable report reviewed on p 293 Prof Cathcart and Mrs Murray reach conclusions supporting the opinion that what is wanted is not so much more food as more intelligent use of it Whether the data presented in the report suffice in themselves to justify such a conclusion may be questioned, but none can doubt at least that sound housekeeping is a very important element in sound nutrition The question is how to secure it, and this is one of the many questions which is now being answered in Soviet Russia differently from elsewhere The Russians in their particular circumstances despaired of efficient private housekeeping and from experiments in supplying canteen meals in time of scarcity they have passed on to the wide spread practice of "social feeding" It may seem a small matter whether people are fed at home or in restaurants, but after reading their clear account[1] of what is being done in the U S S R one sees why Mr Le Gros Clark and Miss Brinton describe this as "one of the greatest cultural experiments the world has seen." The experiment is still an experiment, for as food becomes more plentiful the Soviet citizen may return to his domestic habits But there are undoubtedly big advantages in centralising food consumption "A civilised community, it is insisted, does not waste its labour, time, and fuel. It has something better to do—unlimited creative work, and the enjoyment of the fullest leisure it can win for itself" It has been calculated that on the old family system cooking, laundry, and the care of children required the services of 30 million Russians for a 10 hour day Collective methods mean a saving of something like five sixths in the labour of cooking, which is important in itself to a country struggling to make good But it has an even greater importance if by the application of scientific methods everyone can have not only sound food, well cooked food, and attractive food but even the right kind of food for his occupation or his digestive capabilities In Soviet Russia there is no large body of unemployed available to fill gaps, and if a worker has to go sick the loss is directly felt by those who employ him. The importance of industrial medicine is thus more apparent in the U S S R than it is here, and correspondingly more attention has been paid to the occupational side of dietetics—so much so that "very soon you will only have to tell the restaurant attendants what your job is and they will serve you with the food best suited to you" (In parentheses it may be noted that the Russian physiologist is supposed to care only for optimum nutrition, he leaves minimum nutrition to the politician) As for weak digestions, it is said that well over half a million employees daily receive "curative diets" in the factory restaurants In the past few years food preparation, including the supply of cooked or partly cooked food by "kitchen factories," has come to be recognised as vital to the State, and those who undertake it receive the honourable title of "engineers of social feeding" Moreover, since "nothing is alive that is not controlled from below by the mass of the people," it is a department of affairs in which the public as consumers are encouraged to take a keen interest If it is true that people who cannot afford adequate food cannot be taught the science of nutrition, it is equally true that a community that is conscious of a growing variety and cheapness in its food supplies can easily be induced to study it both in principle and practice Perhaps this applies as much to our own country as to the U S S R

Le Gros Clark and Brinton begin their book with an excellent 40 page outline of the past and present of the Soviet health service

INSTITUTE FOR THE SCIENTIFIC TREATMENT OF DELINQUENCY —A course of lectures on the psychiatry and psychotherapy of delinquency is being given by Dr Denis Carroll at the West End Hospital for Nervous Diseases, Welbeck street London, W, at 6 45 P M on Thursdays till March 11th *The course which is intended for probation officers and social workers has been arranged by the institute and further particulars may be had from the secretary, 56 Grosvenor street, London, W 1*

PRINCIPLES OF MEDICAL STATISTICS

V.—PROBLEMS OF SAMPLING: AVERAGES*

THE observations to which the application of statistical methods is necessary are those, it has been pointed out, which are influenced by numerous causes, the object being to disentangle that multiple causation. It must also be recognised that the observations utilised are nearly always only a sample of all the possible observations that might have been made. For instance, the frequency distribution of the stature of Englishmen—i.e., the number of Englishmen of different heights—is not based upon measurements of all Englishmen but only upon some sample of them. The question that immediately arises is how far is the sample representative of the population from which it was drawn, and bound up with that question, to what extent may the values calculated from the sample—e.g., the mean and standard deviation—be regarded as true estimates of the values in the population sampled. If the mean height of 1000 men is 169 cm. with a standard deviation of 7 cm., may we assert that the values of the mean and standard deviation of all the men of whom these 1000 form a sample are not likely to differ appreciably from 169 and 7? This problem is fundamental to all statistical work and reasoning; a clear conception of its importance is necessary if errors of interpretation are to be avoided, while a knowledge of the statistical technique in determining errors of sampling will allow conclusions to be drawn with a greater degree of security.

ELIMINATION OF BIAS

Consideration must first be given, as previously noted, to the presence of selection or bias in the sample. If owing to the method of collection of the observations, those observations cannot possibly be a representative sample of the total population then clearly the values calculated from the sample cannot be regarded as true estimates of the population values, and no statistical technique can allow for that kind of error. If the average daily consumption of calories per man value is found to be 3000 in a group of 200 families from whom particulars are collected of their week's consumption of food, it cannot be deduced that that value is likely to be the true average of all families. Housewives who are willing to undertake the task of giving such particulars may be above the average level of intelligence or be the more careful and thrifty of the population. The sample is, then, not a representative but a somewhat selected sample, and there is no evidence as to the degree to which this selection affects the results. That difficulty of interpretation has been discussed in a previous section. In the present discussion we will presume that the sample is unselected and devote attention entirely to the problem of the variability which will be found to occur from one sample to another in such values as means, standard deviations, and proportions due entirely to what are known as the "errors of sampling." Attention may first be given to the mean.

THE MEAN

Let us suppose that we are taking samples from a very large population or universe and that we know that an individual in that universe may mean are any value from 0 to 9—e.g., we may be recording the number of attacks of the common cold suffered by each person during a specified period, presuming 9 attacks to be the maximum number possible. The mean number of attacks per person and the standard deviation in the whole population we will presume to be known; let the average number of attacks per person be 4·50—i.e., the total attacks during the specified period divided by the number of persons in the universe—and the standard deviation be 2·87 (as found in the previous section by calculating

* On line 18 of last week's article in this series the figure should be 37·2 (years) and not as printed.—ED. L.

how much the experience of each person deviates from the average, finding the average of the squares of these deviations, and the square root of this value) From that universe we will draw at random samples of 5 individuals From each sample we can calculate the mean number of attacks suffered by the 5 individuals composing it To what extent will these means in the small samples diverge from the real mean—i e , the mean of the universe, 4 50 ?

In Table IV are set out a hundred such samples of 5 individuals drawn at random from the universe [1] For instance in the first sample there were 3 individuals who had 2 colds each, one fortunate one who had none, and one unfortunate who had 4 From each of these samples a mean can be calculated which, in all, gives one hundred mean values , and of these means we can make a frequency distribution In the first sample the mean is 2+2+2+0+4−5=2 0, in the second it is 7 2, and so on The distribution of the means is given in Table V, column (2) There was one sample in which the mean was only 1 2 and one in which it was as high as 7 4 (the possible minimum and maximum values are, of course, 0 and 9) A study of this distribution shows

TABLE V —*Mean Number of Colds per Person in Samples of Different Size*

(1) Value of mean in sample	(2) Samples of 5	(3) Samples of 10	(4) Samples of 20	(5) Samples of 50
	Frequency with which mean values as shown in column (1) occurred

5 75–	6	8	2	—
6 25–	7	3	—	—
6 75–	4	—	—	—
7 25–7 75	1	—	—	—
Total number of means	100	100	100	100
Total observations	500	1000	2000	5000
Grand mean	4 43	4 61	4 50	4 48

(*a*) That with samples of only 5 individuals there will be, as might be expected, a very wide range in the values of the mean , the mean number of attacks of the whole 500 individuals is 4 43 which is very close to the mean of the universe sampled—namely, 4 50 (as given above)—but in the individual samples of 5 persons the values range from between 0 75 and 1 25 (the one at 1 2) to between 7 25 and 7 75 (the one at 7 4) *In samples of 5 therefore, there will be instances, due to the play of chance, in which the observed mean is far removed from the real mean*

(*b*) On the other hand these extreme values of the mean are relatively rare, and a large number of the means in the samples lie fairly close to the mean of the universe (4 50)—39 per cent of them lie within three quarters of a unit of it (i e , between 3 75 and 52 5)

When in place of samples of 5 individuals a hundred samples of 10 individuals were taken at random from this universe, the distribution of the means in these samples showed a somewhat smaller scatter—as is shown in column (3) of Table V The extreme values obtained now lie in the groups 1 75–2 25 and 6 25–6 75 and 58 per cent of the values are within three quarters of a unit of the real mean—i e , the mean of the universe

When 100 samples of 20 were taken (column 4) the scatter was still further reduced , the extreme values obtained lay in the groups 2 75–3 25 and 5 75–6 25 and 77 per cent of the values lay within three quarters of a unit of the real mean With samples of 50 (column 5) there were 91 per cent of the means within this distance of the true mean and 45 per cent lay in the group 4 25–4 75—i e , did not differ appreciably from the real mean Outlying values still appeared, but appeared only infrequently

TWO FACTORS IN PRECISION

These results show, what is indeed intuitively obvious, that the precision of an average depends, at least in part, upon *the size of the sample* The larger the random sample we take the more accurately are we likely to reproduce the characteristics of the universe from which it is drawn The size of the sample, however, is not the only factor which influences the accuracy of the values calculated from it A little thought will show that they must also depend upon the *variability of the observations in the universe* If every individual in the universe could only have one value—e g , in the example above every individual in the universe had exactly 3 colds—then clearly, whatever the size of the sample, the mean value reached would be the same as the true value If on the other hand the individuals could have values ranging from 0 to 900 instead of from 0 to 9 the means of samples could, and would have considerably more variability in the former case than in the latter The accuracy of a value calculated from a sample depends therefore upon two considerations

(*a*) The size of the sample

(*b*) The variability within the universe from which the sample is taken

The statistician's aim is to pass from these simple rules to more precise formulæ, which will enable him to avoid drawing conclusions from differences between means or between proportions when in fact these differences might easily have arisen by chance

MEASURING VARIABILITY

As a first step we may return to Table V and measure the variability shown by the means in the samples of different sizes So far we have illustrated that variability by drawing attention to the range of the means and, roughly, the extent to which they are concentrated round the centre point , a better measure will be the standard deviations of the frequency distributions The results of these calculations are shown in Table VI

The standard deviation, or scatter, of the means, round the grand mean of each of the total 100 samples, becomes, as is obvious from the frequency distributions, progressively smaller as the size of the sample increases It is clear, however, that the *standard deviation does not vary directly* with the size of the sample , for instance increasing the sample from 5 to 50—i e , by ten times—does not reduce the scatter of the means by ten times The scatter is, in fact reduced not in the ratio of 5 to 50 but of $\sqrt{5}$ to $\sqrt{50}$—i e , not ten times but 3 16 times (for $\sqrt{5}=2\ 24$ and $\sqrt{50}=7{\cdot}07$ and 7 07/2 24 = 3 16) This rule is very closely fulfilled by the values of Table VI , the standard deviation for samples of

---

[1] The 'universe' actually used for this and later demonstrations was a publication entitled Random Sampling Numbers arranged by L H C Tippett (Tracts for Computers No XV Camb Univ Press 1927) Sets of unit random numbers were taken from its columns in fives tens twenties and fifties as required

5 is 1 36 and this value is 3 09 times the standard deviation, 0 44 with samples of 50 The first more precise rule therefore is that the accuracy of the mean computed from a sample does not vary directly with the size of the sample but with the square root of the size of the sample In other words if the sample is increased a hundredfold the precision of the mean is increased not a hundredfold but tenfold

TABLE VI —*Values Computed from the Frequency Distributions of Means given in Table V*

Number of individuals in the sample	The mean or average of the 100 means	The variability or standard deviation of each 100 means.	The standard deviation of the observations in the population sampled ÷ square root of size of sample
5	4 43	1 36	1·28
10	4 61	0 91	0 91
20	4 50	0 61	0 64
50	4 48	0 44	0 41

As the next step we may observe how frequently in samples of different sizes means will occur at different distances from the true mean For instance it was pointed out above that with samples of 5 individuals 39 per cent of the means lay within three quarters of a unit of the true mean of the universe The grand mean of these 100 samples 4·43 is not quite identical with the true mean of the universe 4 50 as of course the total 500 observations are themselves only a sample; it comes very close to it as the total observations are increased—it is 4·48 with 100 samples of 50 Instead therefore of measuring the number lying within three quarters of a unit or one unit of the grand mean (or true mean taking them to be to all intents and purposes identical) we may see how many lie within the boundary lines grand mean plus the value of the standard deviation and grand mean minus the value of the standard deviation —i.e 4 43+1 36=5 79 and 4 43−1 36=3·07 The calculation can be made only approximately from Table V but it shows that some two thirds of the means will lie between these limits If we extend our limits to grand mean plus *twice* the standard deviation and grand mean minus *twice* the standard deviation —i e 4 43+2 (1 36) =7 15 and 4 43−2 (1 36)=1 71—*it will be seen that* these include nearly all the means of the samples *only about* 3 *per cent* lying beyond these values (*according to theory we expect* 5 *per cent* beyond ± *twice the standard deviation*) Roughly the same results will be reached if these methods are applied to the larger samples *Our conclusions are* there fore:

(*a*) If we take a series of samples from a universe then the *means* of those samples will not all be equal to the true mean of the universe but will be scattered around it

(*b*) We can measure that scatter by the standard deviation shown by the means of the samples *means* differing from the true mean by more than twice this standard deviation above or below the true mean will be only infrequently observed

DEDUCING THE STANDARD DEVIATION

In practice however we do not know this standard deviation of the means for we do not usually take repeated samples We take a single sample say of patients with diabetes and we calculate a single mean say of their body weight Our problem is this: how precise is that mean—i e how much would it be likely to vary if we did take another equally random sample of patients? What *would* be the standard deviation of the means if we took repeated samples? It can be shown that the standard deviation of means of samples is equal to *the standard deviation of the individuals in the population sampled* divided by the square root of the number of individuals included in the sample (usually written as $\sigma/\sqrt{n}$) These values have been added to Table VI (right-hand column) and it will be seen that they agree very closely with the standard deviations calculated from the 100 means themselves (they do not agree exactly because 100 samples are insufficient in number to give complete accuracy) With this knowledge we can conclude as follows the mean of the universe is 4 50 and the standard deviation of the individuals within it is 2 87 (see above) if we take a large number of random samples composed of 5 persons from that universe the means we shall observe will be grouped round 4 50 with a standard deviation of $2\ 87/\sqrt{5}$; means that differ from the true mean 4 50 by as much as plus or minus twice $2{,}87/\sqrt{5}$ will be rare If we take a large number of samples of 50 then the means we shall observe will be grouped around 4 50 with a standard deviation of $2\ 87/\sqrt{50}$ and means that differ from 4 50 by as much as plus or minus twice $2\ 87/\sqrt{50}$ will be rare

The final step is the application of this knowledge to the single mean we observe in practice In the previous section the mean systolic blood pressure of 566 males (drawn from the area in and around Glasgow) was given as 128 8 mm We want to determine the precision of this mean—i.e how closely it gives the true mean blood pressure of males in this district

Suppose that the true mean is x Then from the reasoning developed above we know that the mean of a sample may well differ from that true mean by as much as twice $\sigma/\sqrt{n}$ where σ is the standard deviation of the blood pressures of individuals *in the universe from which the sample was taken and n is the number* of individuals in the sample it is not likely to differ by more than that amount—i.e our observed mean is likely to lie within the range $x \pm 2\,(\sigma/\sqrt{n})$ Clearly however we do not know the value of σ and as an estimate of it we must use the standard deviation of the values in our sample It must be observed that this *is* only an estimate for just as the mean varies from sample to sample so also will the standard deviation But the latter varies to a slighter extent and so long as the sample is fairly large the estimate is a reasonable one and unlikely to lead to any serious error In the example cited the standard deviation of the 566 measures of systolic blood pressure was 13·05 We therefore estimate that the standard deviation of *means* in samples of 566 would be $13{\cdot}05/\sqrt{566} = 0\ 55$

We may conclude (presuming that the sample is a random one) that our observed mean may differ from the true mean by as much as ± 2 (0 55) but is unlikely to differ from it by more than that amount In other words the true mean is likely to lie within the limits of 128 8 ± 2 (0 55) or between 127 7 and 129 9 for if it lay beyond these points we should be unlikely to reach a value of 128 8 in the sample

The ± value is known as the *standard error* of the mean and is used as a measure of its precision The estimation is clearly inapplicable if the sample is very small for the substitution of the standard deviation of the few observations in the sample in place of the standard deviation of the whole universe from which the few observations were taken may be a serious error With small samples different methods must be applied

Sometimes in published work *probable errors* are given in place of standard errors The former (which has no advantage over the latter) is merely the standard error multiplied by 0 6745 If the variability likely to be observed is ± twice the standard error it will clearly be ± thrice the probable error, for the latter is, approximately, only two-thirds of the former

The origin of the factor 0 6745 is this We previously calculated the number of means of samples that lay within the limits "grand mean plus once the standard deviation" and "grand mean minus once the standard deviation" If, instead, we calculated the number of means that lay within the limits "grand mean plus 0 6745 times the standard deviation" and "grand mean minus 0 6745 times the standard deviation" we should expect to find that precisely half the means lay within these limits and half lay outside them If, therefore, we took a single sample it would be an even chance that its mean did not differ from the real mean by more than 0 6745 times the standard deviation

Summary

In medical statistical work we are, nearly always, using samples of observations taken from large populations The values calculated from these samples will be subject to the laws of chance—e g , the means, standard deviations, and proportions will vary from sample to sample It follows that arguments based upon the values of a single sample must take into account the inherent variability of these values It is idle to generalise from a sample value if this value is likely to differ materially from the true value in the population sampled To determine how far a sample value is likely to differ from the true value a standard error of the sample value is calculated The standard error of a mean is dependent upon two factors—viz , the size of the sample, or number of individuals included in it, and the variability of the measurements in the individuals in the universe from which the sample is taken This standard error is estimated by dividing the standard deviation of the individuals in the sample by the square root of the number of individuals in the sample The mean of the population from which the sample is taken is unlikely to differ from the value found in the sample by more than plus or minus twice this standard error This estimation is, however, not applicable to very small samples, of, say, less than 20–30 individuals, and must be interpreted with reasonable caution in samples of less than 100 individuals

SPECIAL ARTICLES

THE NEW RESEARCH LABORATORIES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

ON Monday last the Hunterian Museum in Lincoln's Inn was closed for an indefinite period (perhaps till the middle of March) in order to expedite the building of laboratories, which has just begun, to house the scientific staff and research workers of the Royal College The reasons which prompted the Bernhard Baron trustees to make their gift of £25,000 last May were the difficult conditions under which work was then being carried out, and the conviction that better accommodation for research work would lead to an increase in medical and surgical knowledge. Work is to be pushed forward with all possible speed and it is hoped to have the Bernhard Baron laboratories ready for occupation in the coming autumn The scheme consists in the demolition and remodelling of the internal structure of the floors above the level of the College library and the erection of two towers (shown on the elevation reproduced in Fig 1), one at each end of the existing fourth and fifth floors The roof will be removed and re erected in such a way that additional laboratory space will be provided on the sixth floor Plans of these three floors as they will be when finished are given in Fig 2

SIXTH FLOOR

Commencing on the east side will be found the animal room sufficient for the accommodation of experimental animals necessary for research work This room is not as large as might be expected in laboratories of this size for the simple reason that stocks of experimental animals and animals recovering from operations are ordinarily housed at the Buckston Browne surgical research farm at Downe The animal room will be finished in white tiles and will have one wall, made of glass and steel, which can be opened completely in summer weather It faces south and is adequately ventilated by roof lights. The animal kitchen, food store and cage sterilising room are in a corridor immediately outside the animal room In the food store provision is made for refrigeration and bin storage of bulk foods The cage sterilising room has a vat sufficiently large to contain and sterilise the largest cage in use A staff kitchen is situated immediately outside the common room set apart for the use of members of the scientific staff and research workers This room provides a central place where workers can discuss their problems and meet those interested On the southern aspect of this room is a sliding folding window, 16 feet in length, capable of being thrown open during the summer There will be an open fire and book shelves

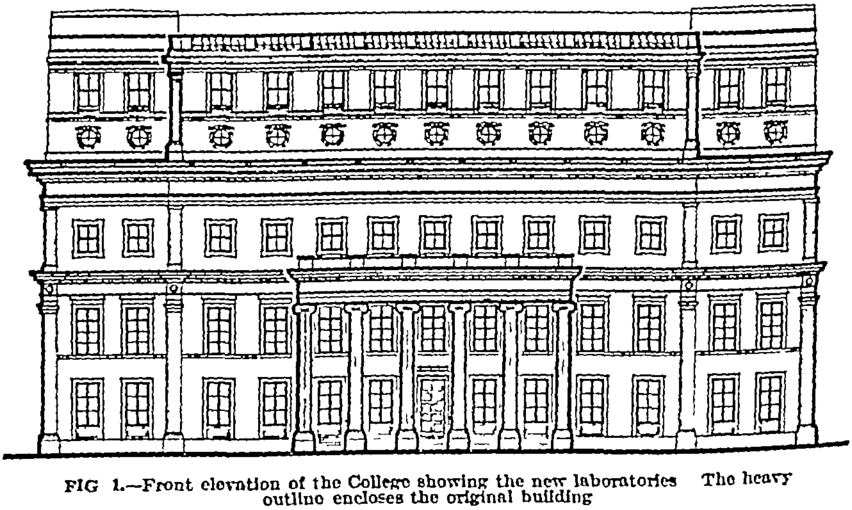

FIG 1.—Front elevation of the College showing the new laboratories The heavy outline encloses the original building

for current periodicals Three small specimen laboratories are for isolated organ experiments and biochemical work then comes the balance and colorimeter room and a small study for the worker who wishes privacy while reading or writing up a piece of work.

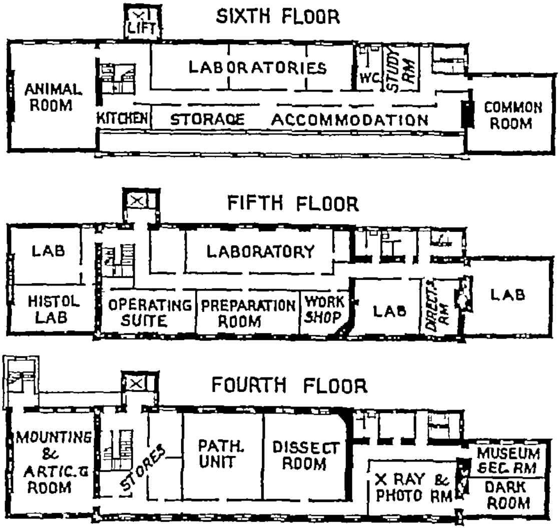

FIG. 2.—Plans of the three new floors.

FIFTH FLOOR

Beginning at the east end is the histological laboratory and a room for the assistant conservator The operating suite comprises theatre with adjacent sterilising room opposite to which on the other side of the corridor is the changing room complete with shower bath and clothes cupboards. The theatre will be tiled with terrazzo flooring To eliminate danger of fire and anæsthetic explosions all electrical switch gear in these rooms will be of mercury and enclosed Compressed air and vacuum services are available for the anæsthetist and operator Next the sterilising room is the main autoclave and water sterilising plant the room also being used for the preparation of laboratory solutions sterilising of dressings &c On the other side of the corridor is a large acute experimental laboratory fitted with kymographs and physiological equipment Adjoining is a room for the smoking and varnishing of drums The workshop for metal and wood working is a necessary provision when large amounts of apparatus are in use The director's laboratory will contain a completely electro magnetically screened cubicle to house the cathode ray oscillograph equipment Alongside is his private room. Another large experimental laboratory completes this floor

FOURTH FLOOR

On this floor is housed the scientific staff of the museum with ample storage space The large east room *is for the* mounting and articulating of pathological and anatomical specimens. The pathological curator's room communicates with the *laboratory where all the pathological* work will be done The anatomical laboratory is for use in the preparation of dissections. The X ray unit is in a separate room out of which opens the dark room The floor is completed by the cataloguing room and a room for the museum secretaries.

The Equipment

An outstanding feature of the new laboratories is the method whereby plasticity of arrangement has been obtained. The furniture—benches cupboards, drawers—is built in standard units which can easily be moved and refixed where necessary Apparatus can be placed in the most suitable position and the whole contents of a room rearranged The only fixed points are the sinks. Electric light, gas vacuum and compressed air points are arranged on the walls in convenient positions, and in the large laboratories trap doors in the floor allow of access to electric, gas and water points so that experiments if necessary can be arranged and carried out well away from the surrounding walls With the exception of the animal rooms operating and sterilising rooms the new floors are laid throughout in Queensland jarrah wood strips and partition wall are built of expanded metal and plaster Rearrangement of rooms would *therefore* be a simple matter should it become necessary The X ray equipment will serve cineradiography as well as the routine X ray investigations. The main characteristics of the design and equipment have been utility and simplicity

Structural alterations to the main College building are required to carry the increased weight of the laboratories but when the scheme is finished these will not be apparent The external appearance will in fact be improved by the new towers which bring the building back again to the original double cube design of Sir Charles Barry who was the first architect of the present structure Barry's original block was a *perfect double cube and the new building closely* approximates to these proportions

The architects are Messrs Lanchester and Lodge and the contractors Messrs Higgs and Hill.

MEDICINE AND THE LAW

Damages against Nature Cure Practitioner

ON the fifth day of the trial in the case of Sones v Foster the jury awarded the plaintiff £400 damages for the negligence of the defendant a nature cure practitioner Mr Sones a man aged about 9 suffered in August 1935 from a gangrenous left foot the condition being due to sepsis following a corn He consulted Mr Foster on August 17th and was advised that frequent treatments would be necessary For this reason he went to Mr Foster's house for several weeks at a charge of 8 guineas a week According to Mr Sones the treatment included painful scrubbing with a nail brush the cutting away of skin the immersion of the foot in almost boiling water and the snipping off of a toe Mr Foster on the other hand said that he devoted himself to improving the patient's general health (which was very bad) so as to prepare him for the operation of removing his foot which he never had any hope of saving After 9 weeks in Mr Foster's house the plaintiff was taken, on Oct 22nd, to St Bartholomew's Hospital where his leg was amputated above the knee next day There was considerable dispute as to the exact state of Mr Sones when Mr Foster first saw him, as to the degree of progress made by the patient in Mr Foster's house, and as to the assurances of improvement which Mr Foster was alleged to have given to his patient As the trial proceeded, it seemed that the issue would be whether or not, through Mr Foster's fault, operation had been delayed with the result that Mr Sones's leg was amputated above the knee instead of below the knee This was perhaps an awkward surgical problem for Mr Foster, whose qualifications were membership of the British Association of Naturopaths, membership of the Association of Medical Herbalists, and membership of the Health Practitioners' Association The experts called on behalf of Mr Foster included Mr Arthur Barker, a herbal practitioner, who, having heard Mr Foster's description of his treatment, deemed it correct, and Dr J A C Braun, who said he had removed his name from the Medical Register in 1935 in order that he might be free to write and lecture as he pleased Dr Braun's evidence was that it was in any case preferable to amputate the patient's leg above the knee even if the surgeon felt he could safely take the leg off below A man did not always have better movement if his knee was saved than if he lost it, if amputation was in any case necessary just below the knee amputation above the knee had every advantage, the condition of arterio-sclerosis confirmed his view During discussions between Mr Justice Atkinson and the counsel in the case, it seems to have been agreed that a naturopath is not expected to show any higher degree of skill than similar practitioners profess, but that, if he steps out of his vocation and undertakes treatment when he knows he can do no good, then he is liable The jury seems to have found that Mr Foster represented himself to be a naturopath of a high order, and that judged by that standard, he had been guilty of negligence in the advice and treatment which he gave to Mr Sones The sum of £490 which their verdict awarded was made up of £40 for the return of fees which the plaintiff had paid, £50 for unnecessary pain suffered by him, and £400 for the loss of his knee

Visitors to courts of law are sometimes intrigued by exhibitions of judicial nescience A judge is allowed to know the points of the compass and the daily rising and setting of the sun Counsel must be careful not to take too much else for granted, many matters of common knowledge must be strictly proved and not merely assumed Mr Justice Atkinson, in summing up to the jury, refrained from taking shelter behind the walls of judicial ignorance Although he said, the orthodox medical profession liked to think itself the sole repository of knowledge connected with the healing art, there were undoubtedly unorthodox practitioners rendering great public service, professional osteopaths and naturopaths were an example The present day appreciation of the benefits of fasting was due to the naturopaths it was wrong to disparage these practitioners nobody need consult them unless he liked The learned judge mentioned the statute of 34 & 35 Henry VIII, still unrepealed, which is sometimes called the Herbalists' Charter though the preamble hints that the non-academic practitioners thereby to be protected are those who have ministered to poor people only for neighbourhood and God's sake and of pity and charity" If the law has stood still since the statute was passed, medicine and surgery have made some modest progress in the meanwhile If courts are anxious to delve into the archæology of statutory references to medicine, there is another Act of Henry VIII (also still unrepealed) which expresses concern because "common artificers, as smiths weavers and women, boldly and accustomably take upon them great cures to the grievous hurt, damage and destruction of the King's liege people and especially of them that cannot discern the cunning from the uncunning" In Sones *v* Foster the plaintiff's counsel probably did not omit to point out that Mr Foster had undertaken a surgeon's task with a herbalist's qualifications The judge may on this account have felt the stronger impulse to defend unorthodox practitioners, he has to see fair play As for distinguishing the cunning from the uncunning or, as the Medical Act puts it, the qualified from the unqualified, there was a suggestion that Mr Foster had unjustifiably represented himself to be a fully qualified doctor As this allegation did not specifically appear upon the plaintiff's pleadings, the court refused to allow evidence to be given on the point Mr Foster agreed, in cross examination, that he was not entitled to use the letters "M D" A circular whereon his signature was followed by the letters "M.D S F" was put to him He explained that the initials stood for Member of the Democratic Socialist Federation, it was a printer's error that there was a gap between the "M D" and the "S F", the circular was destroyed on that account Questioned about documents referring to an agreement with a gas company, he admitted that the words "medical practitioner," describing him, were in his own handwriting But when pressed about the letters "M D" which followed his signature to the agreement, he insisted that they were "N D" and not "M D", the "N D" stood for Diploma in Nature Cure Well, it is all very confusing

Ambulance Service and Hospital Rules

At a recent inquest in Plymouth, where the deceased had been injured in a traffic accident, it was stated that a new rule had been made locally to the effect that on particular days of the week the traffic casualties should (except in serious cases) be taken to particular hospitals It was said that, though this rule had been in force since Jan 1st, neither the police nor the ambulance drivers concerned were aware of it The ambulance took the injured man to the Prince of Wales's Hospital, Devonport, in accordance with the usual orders to take the cases to the nearest hospital. Arriving at the Devonport Hospital at 6 10 P M, the ambulance driver was told that already one accident case was being dealt with in the casualty ward and that the injured man should have been taken somewhere else While waiting in the emergency waiting room, the patient was kept warm and a fresh dressing was applied At 7 38 he was taken to the Lockyer street Hospital where an injection was given He had a fractured leg and a cut eyelid and was suffering from shock He died when about to undergo operation The coroner naturally sought to ascertain whether there had been any failing to treat the man as a serious case on his arrival at Devonport and whether death was accelerated by the removal on the second journey in the ambulance Post mortem examination showed that the patient aged 68, had a weak heart and might have died at any time A verdict was returned that death was due to shock, no blame was attributed to any

(Continued at foot of next page)

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

FROM A PUBLIC HEALTH CLINICIAN

V

KINGS may change but public devotion to the Crown remains largely unchanged similarly the relations of the public to their doctors do not alter materially from year to year In most respects the public obtain from their doctors what they wish They demand medicines and medicines they get. Should any doctor see a patient and advise ever so wisely but not prescribe a medicine patient and friends will be dissatisfied and declare that nothing has been done If a doctor fails to prescribe for his own family it is likely they will seek some tasty or prettily coloured mixture from the local chemist There are indeed a few medicines which have a definite influence on the disease for which they are given and others which may assist a patient to recover more comfortably but the majority alas are of little value Doctors are not magicians or even prophets but just pilots who guide their patients through maladies The doctor merely steers, the patient does the curing

Again the public demand names and causes for their illnesses and names and causes they get. Each day any of us may experience a pang of pain or a discomfort somewhere and it is generally impossible to say exactly why it occurs or to what defect the discomfort is due The position is different with a declared disease but those that consult their doctors for less defined ailments nevertheless demand names and a cause Various terms or phrases have been adopted which satisfy the patient A great favourite is chill; a thorough chill chill of liver stomach kidney heart or nerves Now illness due to chilling may occur and pains may well follow exposure to draught as those in the neck or back after a motor drive or due to some exposure during the night in a cold bedroom but the word chill is used in addition to cover a host of undiagnosable minor ailments Rheumatism is popular and neuritis and last but not least, comes influenza to cover a variety of conditions especially febrile attacks due to infection with a known or unknown germ

It may be said that doctors prescribe unnecessary medicines or that one has wrongly diagnosed as neuritis something which a colleague distinctly said was a 'chill; but let patients remember that these mischances happen because they demand medicines and names

Fashions in treatment come and go bleeding is succeeded by polypharmacy which in turn gives way to dietetics Fashions in diagnosis also change suppressed gout we no longer hear of visceroptosis has almost passed and even colitis of various kinds has become less common There are also ætiological fashions. In the Victorian era excessive smoking was a common cause to which ills were attributed but now that excessive smoking is far commoner we hear much less of this factor maybe because the doctors are among the worst sinners Except for tobacco amblyopia and cancer of the tongue there are few disabilities that can rightly be attributed to this excess There are those who would attribute duodenal ulcer to this cause and perhaps they are right the case does not yet seem proven but to depend mainly on the obiter dicta of great men—a very dangerous basis For those who would attribute thrombo angitis obliterans to tobacco smoking I feel little sympathy To prove that a very rare disease is due to a very common habit necessitates remarkably sound arguments the case to day is even more shadowy than Karl Pearson s statistical suggestion that the decline in tuberculosis was due to the increase in the British Navy The victimisation of the large intestine for alleged metabolic misdeeds was perhaps merely a personal albeit a dangerous idiosyncrasy but even constipation to day has lost its quondam popularity No doubt the pendulum will *swing again*

Perhaps we are all too ready to accept plausible ætiological explanations as are botanists or ornithologists ready to accept somewhat fanciful if not poetical suggestions as the reason for the existence of structural features The cessation of the dread summer diarrhœa has been attributed to the extension of pasteurisation of milk but yet the disease has slackened or ceased in districts where there is no pasteurisation A bright colleague suggested to me that diarrhœa and possibly some other disabilities had gone as the horses on the roads became fewer that may indeed be a factor but I would give a more prominent place to the extension of road tarring which also has perhaps diminished summer epidemics of septic sore-throat

It would be interesting if this question of ætiology were considered from a different angle Instead of seeking to explain certain morbid happening some one with the time to spare might review the changes that have taken place in our environment and habits—such as road tarring or motoring—and work out what results may be reasonably related thereto

* * *

The science of meteorology covers a wide field Most of us are aware of the activities of meteorologists only as made known through weather reports and from the shrewd prophecies heard on the air Some doctors may tap barometers or even keep rain gauges but they are for the most part entirely unfamiliar with the formation and movements of cloud or even the method of judging the velocity of air currents by the movement of small medium or large trees Into the activities of the meteorological society I received a baptism when in a rash moment I promised to act as phenological observer for district

---

(Continued from previous page)

body Medical witnesses said that it was a pity that he was not kept at Devonport for treatment but that the delay in treatment did no harm There were two doctors at the hospital one on duty A case of this kind would have needed two doctors and if the patient had been admitted it would have been necessary to keep him warm and quiet for some time before the operation in any event The coroner accepted this evidence but rightly thought any change in the rules for admitting traffic casualties should be made fully known to the police and the ambulance service

COLLEC

A 50 First appearances had to be reported of a large number of plants, migrant birds, butterflies, and insects, to say nothing of frog spawn and the first songs of certain birds It seemed an interesting pastime and I attempted to organise the district through schools and natural history societies as well as keeping all agog my own eyes and ears The result was satisfactory but the duties were too onerous, the task far too great for any busy man, and I abandoned the work after a year with a feeling of relief, a great weight was lifted—it was as if some miraculous message had been received from the commissioners for the Inland Revenue that they would forgo my income tax for 1937 No longer was it necessary to keep one eye constantly on the calendar and the other glued to hedges, fields, woods, marshes, and ponds

Yet the preoccupation carried the compensation that it led me along various meteorological highways and by ways that would never otherwise have been traversed Like many others I bemoan a failing memory and the lack of time and capacity to explore many enchanting fields

* * *

The art of chairmanship and the art of being a secretary are both useful to doctors in their many sided duties Having been chairman or secretary of various bodies, councils, or committees for over 40 years and having made, in one or other capacity, most of the mistakes that it is possible to make, the rudiments of the art are now becoming familiar to me and I have come to realise that good chairmen and good secretaries are born rather than made But, granted a certain innate flair for the work, unceasing education is still necessary if excellence is to be achieved or maintained (And, in parentheses, though some may not agree, I believe the art of letter writing takes a deal of learning)

Certain principles must guide both chairman and secretary, they must be prepared to let others reap the credit for their own ideas and they must avoid sharp retorts The caustic remark, the acid retort, so easy to make (we see them in all the comic papers), yet so difficult to recall, are prone to transport a discussion from the plane of reason to that of emotion Yet chairman or secretary must be prepared to be firm and to reach swift and equitable decisions There are no rigid rules, although there may be relatively rigid rules Some meetings are best guided by permitting heterogeneous speeches, others by keeping everyone strictly to the point A word or two of explanation or a smile will often maintain better control than blows with the chairman's mallet Much have I learnt and much am I still learning from individual tacticians following their individual tactics One able man, wishful to put through difficult and disputed decisions, would begin straight away by quarrelling and making libellous remarks until angry words were bandied and faces became redder, then came a reaction, everyone regretted their excesses, time was passing, and all the controversial matters were decided amicably and according to the wishes of the quarrel some diplomat Lord Askwith seemed to give every one a free hand to talk as much as they liked and about anything they wished, yet at crucial points, when the right atmosphere had been secured, he was always a tower of strength

But this is not an essay on chairmanship and I must hand on the torch of "Grains and Scruples" to my anonymous, but certainly worthy, successor

Maj H Williamson, O B E, to be Lt Col

NEW SCHEME AT FROME VICTORIA HOSPITAL.—Since this hospital was built in 1900 there has been a scheme by which members contributed first a halfpenny and then a penny a week As this is now quite inadequate, a new scheme has been evolved by which married men pay *3d* a week to cover husband wife, and children under 16 who are not employed, young people between 16 and 18 pay *1d* a week and single adults *2d* The scheme covers treatment at several hospitals

WEST SUFFOLK AND IPSWICH HOSPITAL —Sir Bunnell Burton, of Ipswich, and Sir William Churchman of Melton have agreed to share between them the cost of building an orthopædic department and fracture clinic at this hospital The cost is estimated at £6000 Recent extensions and modernisations had absorbed all available funds and the hospital board was committed to the orthopædic scheme by arrangement with the local authorities

CORRESPONDENCE

THE WILL OF THE LATE SIR HENRY WELLCOME

To the Editor of THE LANCET

SIR,—As the trustees appointed by the will of the late Sir Henry Wellcome we ask you to be good enough to publish this letter in order to clear up any misconception which may have arisen with regard to the effects of the will. We are led to make this statement by the number of appeals for contributions to various research undertakings which have already reached us For reasons mentioned below the trustees will not be able to consider any such applications in the immediate future.

In January 1924 the Wellcome Foundation Limited was formed for the purpose of taking over the whole of the business activities of Burroughs Wellcome and Co and the various scientific research institutions and museums established by the late Sir Henry Wellcome who held the whole of the share capital.

By the terms of the will the shares of the Wellcome Foundation are now vested in us as trustees and the activities of the Foundation throughout the world will be carried on in collaboration with the trustees by a board of directors of which the present governing director is Mr George E Pearson who has been closely associated with the late Sir Henry Wellcome for more than 40 years

It will be realised that owing to the magnitude of the testator's estate a very large sum has to be found for death duties Provision has also to be made for —

(*a*) A Welfare Fund for the benefit of employees of the Wellcome Foundation Ltd. and its associated companies

(*b*) The payment of certain specified annuities to relatives and others personally connected with the testator

(*c*) The erection and maintenance of a building in Minnesota to be dedicated as a memorial to the testator's parents.

Subject to these prior charges the remainder of the divisible profits will be utilised in accordance with the testator's instructions in the following manner —

(1) For the maintenance of The Research Undertaking Charity which is a fund for the advancement of medical and scientific research work in any part of the world conducive to the improvement of the physical conditions of mankind and in particular for the discovery invention, and improvement of medicinal agents and methods for the prevention and cure of disorders and the control or extermination of insect and other pests which afflict human beings and animal and plant life and also for the organisation, equipment and expense of special research expeditions and commissions

(2) For the maintenance of The Museum and Library Charity which is a fund for the establishment or endowment of research museums or libraries in any part of the world and for the collection of information of every kind connected with the history of medicine surgery chemistry bacteriology pharmacy and allied sciences which in the opinion of the trustees may be desirable

This statement of the position has been somewhat delayed by the fact that the testator imposed upon all his trustees the obligation before undertaking the trust to enter into a covenant not to be engaged in or in any way to assist in any concern which carried on a business in competition with Burroughs Wellcome and Co Three of the trustees had no difficulty in entering into this covenant immediately after the testator's death but the two medical and scientific trustees felt that certain words in the covenant might be held to restrict them unduly in the performance of their official and general duties to medical science and to imply their particular concern with the business interests of the foundation The matter has now been considered by the High Court of Justice which has made an order allowing them to enter into a covenant in a form removing any such unacceptable implication and enabling effect to be given to what was known to have been the testator's intention.

No trustee director or any other person holds for himself or in his own right any shares in the Wellcome Foundation and all the divisible profits in each year will be devoted to the various purposes named in the will and indicated above

We believe this to be the first example in this country at least of a testamentary disposition by which the whole of the profits from a great manufacturing and trading organisation after certain personal and memorial bequests have been fulfilled are permanently dedicated to the advancement of knowledge for the general benefit of mankind

We are Sir yours faithfully

PROVISO WHICH, BY ORDER OF THE COURT MAY BE ADDED BY A TRUSTEE TO THE COVENANT REQUIRED OF ALL THE TRUSTEES UNDER THE WILL OF SIR HENRY WELLCOME

PROVIDED that nothing in this Covenant shall be held to prevent me in the exercise of my proper function in any appointment held by me in the public service or under any publicly or privately endowed organisation for the promotion of medical research or under any University in Great Britain from giving advice on scientific matters to any person or persons solely for the purpose of rendering scientific discovery available for the general use and without pecuniary reward or other personal advantage to myself"

INTRADERMAL TESTS IN WHOOPING-COUGH

To the Editor of THE LANCET

SIR,—In your issue of Jan 16th Dr B O Brien and Dr J P J Paton both record experience with intradermal tests in whooping cough. Whereas Dr Paton has had equivocal results Dr O Brien appears to have obtained some correlation between the positive response and a previous history of whooping cough

About a year ago I carried out some intradermal tests and adopted the technique described by Paterson Bailey and Waller[1] using 0 1 c cm. of the Sauer vaccine supplied by E Li Lilly and Co Ltd Readings were taken at 24 and 48 hours The maximum was usually at 24 hours but occasionally the 48 hour reading was greater I have analysed the results according to the standard of Drs O Brien and Paton—i.e. assuming a reaction of 1 cm. or more to be positive

Of 75 children suffering from whooping cough at stages varying from the first week to the third month 49 (65·3 per cent) were positive—a result similar to Dr Paton's I have divided the cases according to whether the test was done in the first three weeks or later, and as the following Table shows, there does appear to be a significant increase in the proportion of positive reactions in the later stages

---

[1] Paterson D Bailey R H, and Waller R G (1935) *Lancet* 2 301.

Period of disease	Positive	Negative
1st–3rd week	17	17
4th week or later	32	9
	49	26

It is doubtful whether this increased sensitivity to the vaccine in the later stages of whooping cough is permanent, for in a control series I could not demonstrate any correlation between the positive response and a previous history of the disease

The controls were 75 children convalescent from other infections, 51 (66 2 per cent) were positive Grouped according to whether or not they had had whooping cough, there was no significant difference in the proportion of positive reactions —

Previous history	Positive	Negative
Whooping cough	18	9
No whooping cough	33	14
	51	23

Generally reactions were of a nondescript type compared with the clear cut responses to the Schick and Dick tests, and difficulty was found in interpreting them In many cases there was a small papule of 5 mm or a faint erythema of 5 to 10 mm—both responses arbitrarily classed as negative I do not think one can dismiss such reactions under 10 mm. as being due to trauma of the needle In other intradermal tests such as the Schick and Dick, it is often difficult to detect even the needle puncture at 24 hours in a negative result, and this applies to young children as well as to adults

Dr O'Brien discusses the possible fallacy of the reaction to the Sauer vaccine occurring in a person sensitive to other members of the hæmophilus group A certain number of the cases I have quoted were controlled by using a vaccine of *H influenzæ* Dr E A Straker of the London School of Hygiene kindly supplied me with a freshly isolated strain, which was made up in the same strength as the Sauer vaccine Reactions from 0 1 c cm intradermally were of a type similar to the pertussis reaction, but always greater, the average diameter being 20–30 mm instead of 10–20 The maximum was at 24 hours, fading at 48 hours Of the cases of whooping cough 33 were tested with *H influenzæ* vaccine, and all but 3 were positive The 3 that were negative were also negative to the Sauer vaccine Of the 17 controls tested all were positive The fact that such reactions were obtained fails to rule out the possibility of there being a group sensitivity to the hæmophilus organisms

It is not surprising that variable results have been reported with these intradermal tests, considering that a vaccine is used containing the whole products of the organism—stable or otherwise Elucidation of the antigenic structure of the Bordet Gengou bacillus may reveal in time some product suitable for clinical use, but at present no reliable agent appears to be available

I am, Sir, yours faithfully,

Farncombe Surrey Jan 23rd J S WESTWATER

TUBERCULOUS ABDOMINAL GLANDS

To the Editor of THE LANCET

SIR,—With reference to the interesting article by Mr Colt and Mr Clark in your issue of Jan 16th on tuberculous disease of the abdominal lymphatic glands, I venture some comments, based on 45 patients admitted to this sanatorium with symptoms, and an undetermined number admitted without symptoms but with tuberculosis of the skeletal system in whom calcified abdominal glands were found by radiography As a result of this experience I have gained an impression, which I have not corroborated, that many cases of tuberculosis of the abdominal glands are not diagnosed and give no other evidence of their presence than a positive tuberculin reaction, and that the cases with symptoms or signs form the minority Nevertheless the presence of tuberculous abdominal glands is often suspected and, if the suspicion is sufficiently strong, my own feeling is that laparotomy is indicated for the purpose of diagnosis rather than for the purpose of treatment A positive diagnosis, supported by pathological examination of a removed gland, affords justification for a course of treatment in an open air hospital to produce quiescence of the disease and to avoid the complications mentioned in Mr Colt's and Mr Clark's article A negative diagnosis will relieve the patient and relatives from the burden of suspicion

The question of operative removal of tuberculous abdominal glands should therefore not arise, as it is a fact, difficult to explain but accepted by those who work in open air hospitals, that an efficient régime of rest in the open air, suitable diet, and light treatment will produce in these cases rapid abatement of symptoms and signs, and progress to recovery free from complications Of the above patients the progress of only one was unsatisfactory, and in her case an additional diagnosis was made of tuberculosis of the cæcum —I am, Sir, yours faithfully,

M. C WILKINSON,

Medical Superintendent, Essex County Council Sanatorium, Black Notley

Jan 25th

LYMPHATIC SPREAD IN RECTAL CANCER

To the Editor of THE LANCET

SIR,—As the author responsible for revising the chapter on diseases of the rectum in Rowlands and Turner's "Operations of Surgery," I cannot agree with your reviewer's dismissal of the section on lymphatic spread in cancer of the rectum (THE LANCET, Jan 23rd, p 209) The "many years' old diagram" is Miles', and it represents his view to day, "modern research" is discussed at considerable length on the opposite page If I could accept the simple creed that everything new is right and everything old is wrong, my work would be easy But since against the statement that "when a growth in this situation is removable, there is no downward spread or extension to the ischiorectal fossa," I must set my personal knowledge of six recent recurrences in this situation after radical operations by competent proctologists, my only course is to state both views as fairly as possible

I am, Sir, yours faithfully,

Harley street W Jan 25th W H OGILVIE

PROTAMINE INSULIN

To the Editor of THE LANCET

SIR,—I shall be glad if you will correct an erroneous impression which might be derived from the brief report in your issue of Jan 16th of my remarks following Dr Hagedorn's lecture on protamine insulin—namely, that Dr Hagedorn had willingly delayed the issue of British made protamine insulin This is far from being the case Dr Hagedorn gave to the manufacturers of "A B" insulin, most promptly and readily, every assistance to enable them to prepare protamine insulin (without added zinc) according to his method Such delay as has occurred has resulted from the desire which prompts all British manufacturers of insulin to avoid the chaos which would ensue if the firms concerned were to issue protamine insulin possessing different degrees of retarded action.—I am, Sir, yours faithfully,

FRANCIS H. CARR.

The British Drug Houses Ltd., Graham-street,
London, N.1, Jan. 27th.

THE LEGAL POSITION OF HERBALISTS

To the Editor of THE LANCET

SIR,—The summing up by Mr. Justice Atkinson in the case of Sones v. Foster, tried in the Court of King's Bench on Jan. 21st, calls, I think, for medical comment. The learned judge is reported in the *Times* to have said that "Herbalists have been recognised legally since the passing of a statute in the reign of Henry VIII which has never been repealed," and as the defendant in the case seems to have claimed to be a herbalist as well as a naturopath the inference to be drawn was that he was exonerated by that Act as far as its application went.

I recall a previous occasion when the learned judge, Mr. Atkinson as he then was, evinced an interest in unqualified practice, for he moved an amendment in the House of Commons on Feb. 9th, 1926, to a motion which I had introduced: "That in the opinion of this House an authoritative enquiry, with the object of making recommendations to Parliament for dealing with the whole position of irregular practice in medicine and surgery, is urgently necessary." Mr. Atkinson's amendment was: "That in the opinion of this House an authoritative enquiry with the object of securing the recognition and registration of manipulative practitioners having approved qualifications is urgently necessary."

With all respect I submit that the learned judge's exposition of the present position of herbalists is inaccurate and his description of the effect of the statute incomplete. The history of this statute is interesting. The first attempt to regulate medical practice in England was made by Act 3 Henry VIII, by which no person was allowed to practise as a physician or a surgeon within the City of London or a radius of seven miles from it without examination or approval by the Bishop of London, or outside that area by the Bishop of the diocese concerned. A curious survival of this prerogative of the bishops is the privilege, still existing but never put into operation, of the Archbishop of Canterbury to confer degrees in medicine. The Act 34 and 35 Henry VIII, which is the Act referred to by the learned judge, was apparently passed to allow certain persons to administer medicines without having the licence from the bishops provided for by the earlier statute.

The permission given by it for herbalists to practise was limited to the use of external applications, or, in the event of internal medication, to the treatment of three specified diseases—stone, strangury, or agues. Judicial interpretations subsequent to the passage of the Act declared limitations further restricting its scope. Thus it was early laid down that its effect is that "it does not extend either in words or intent or meaning to give liberty to any person to practise or exercise for gain or profit. The parties licensed by that statute are such persons as shall be good honest people, as old women and such as are inclined to give their neighbours physic from charity and piety"; and indeed the original Act contained the stipulation that the privilege should be restricted to those who "minister to the sick without fee." As the original Act made no provision for testing the knowledge of the herbalist or for any responsible body to administer the Act it remained practically inoperative, and this circumstance, as well as its implied supersession by later Medical Acts, no doubt explains the omission to repeal it formally.

Surely any claim that the statute of Henry VIII legalises the general practice of medicine and surgery by herbalists and that their position is unaffected by the Medical Acts which have since been placed upon the Statute Book could not be sustained.

I am, Sir, yours faithfully,

House of Commons, Jan. 22nd. E. GRAHAM LITTLE.

PERFORATED GASTRIC ULCER

To the Editor of THE LANCET

SIR,—The annotation on p. 216 of your last issue on the use of "a hollow sound" by Dr. Robert Leclercq in treating a perforated gastric ulcer which could not be sutured, reminds me that it is some seven or eight years since I first employed a similar manœuvre. I do not suppose that the procedure was original on my part, though it is not mentioned in most books on operative surgery. Being faced, like Dr. Leclercq, with a large perforation which could not be closed I introduced into the stomach a large soft rubber catheter which fitted the hole. This was not employed afterwards, however, for emptying the stomach, for I pushed it on into the duodenum and used it for giving the patient large amounts of fluids directly into his alimentary canal. The catheter was brought out through a layer of omentum and then through a stab wound in the abdominal wall. No leakage took place and after a few days, when adhesions had formed, the catheter was removed and the opening quickly healed. I have used the method on two or three occasions since that time with the same success. Small perforations can often be successfully "plastered" with a tag of omental fat, but this method may fail when the perforation is large. The catheter may then be employed with confidence.

There can be few surgeons in this country who would contemplate the alternative of performing a partial gastrectomy in the presence of any perforated ulcer. To save the patient's life is the first consideration, without prejudice to whatever further treatment may be necessary afterwards when the crisis has been passed.

I am, Sir, yours faithfully,

London, Jan. 24th. GEOFFREY KEYNES.

OVERBREATHING TETANY

To the Editor of THE LANCET

SIR,—We were much interested in the two papers by Drs. McCance and Watchorn and Drs. Cumings and Carmichael in your issue of Jan. 23rd. These workers record their failure to confirm some experimental findings published by us last year, and their papers call for some comments.

In the second case recorded by Drs. Cumings and Carmichael the level of the calcium in the cerebrospinal fluid (C.S.F.) rose from 4.2 mg. per 100 c.cm. to 4.4 mg. in eighteen minutes and to 4.8 in the course of twenty-eight minutes. Whilst these workers state that the first alteration is within their limits of experimental error, they do not say whether this applies to the total rise. If it does so their results in no way vitiate our own, for we recorded alterations of only 0.2 mg. per 100 c.cm., and this would fall within their limits of experimental error.

There is no record in their paper of the volumes of C.S.F. used in their estimations of calcium. We ourselves calculated our experimental error in a preliminary series of determinations on known solutions, and reduced it by using 6 0 c cm of fluid in each estimation This necessitated the removal of 15 c cm of C S F from the patient for each determination of calcium and phosphate One of the reasons why we did not take our resting specimens immediately before the period of tetany, but on the previous day, was our fear that we might produce severe post lumbar puncture headaches in our patients if we removed as much as 30 or 45 c cm of C S F within half an hour The other reason was that our first patient seemed to develop symptoms of tetany gradually, and had premonitory symptoms and signs such as paræsthesiæ and Chvostek's sign for four or five hours before overbreathing brought on carpopedal spasm and laryngismus stridulus It seemed reasonable to assume that during this period changes in the diffusible calcium might already have been occurring

If this alteration recorded by Drs Cumings and Carmichael in the C S F calcium is outside their limit of experimental error it becomes of importance, for it shows that changes were occurring in the level of the C S F calcium during that period of twenty-eight minutes—although in a direction opposite to that recorded by ourselves

Clearly determinations of the ultrafiltrate calcium of the serum were desirable in our patients, but we had not the facilities for overcoming the great practical difficulties involved in such estimations—as, for example, keeping the serum in gaseous equilibrium throughout the ultrafiltration We were therefore interested to read that Drs McCance and Watchorn had performed this determination (presumably on serum, although this is not made clear by them) but regret that experimental details were not given

If one sets aside theoretical considerations as to the mechanism by which the C S F is formed, on which we do not find ourselves in agreement with these workers, the experiments of Drs McCance and Watchorn suggest that the drop which we found in the C S F calcium was not related to the tetany itself. Were this the case the changes found by us and by Drs Cumings and Carmichael would indicate that the calcium content of this fluid does not remain constant for any individual, but varies by as much as 10 or 12 per cent from day to day and from hour to hour This would be of great importance in the interpretation of the work which has been done, and is being done, on the calcium content of the C S F in other conditions

We are not aware that such variations have been reported.

We are, Sir, yours faithfully,

C G BARNES,
R I N GREAVES

Hammersmith road, W Jan 25th.

WAS SHERLOCK HOLMES A DRUG ADDICT?

To the Editor of THE LANCET

SIR,—I am writing to comment upon a recent reference in your columns concerning the character of Sherlock Holmes, the fictional creation of my father, the late Sir Arthur Conan Doyle, M.D

Your contributor's interesting notes on cocaine poisoning give the erroneous impression that Holmes was a "drug addict." As a matter of actual fact, my father neither conceived nor depicted Sherlock Holmes as a drug addict He was represented as one of those rare individuals who use drugs sparingly and occasionally, and who are the masters rather than the slaves of the drug concerned

It would be superfluous for me to emphasise the differentiation between the two categories

I am, Sir, yours faithfully,

Jan 9th DENIS P S CONAN DOYLE.

HOSPITAL AMALGAMATION IN LIVERPOOL

To the Editor of THE LANCET

SIR,—The alterations in the Liverpool United Hospital Bill, of which the secretary of the Associated Voluntary Hospitals Board gives particulars (p 232), are interesting, especially the exclusion of the purchase of surgical instruments and appliances from the purview of the medical board. As regards the representation of sections of the medical staff on the board my letter, in spite of the secretary's assertion to the contrary, stated clearly that "there is a power to coöpt within limits of particular offices set forth in a schedule" The point, of course, is whether the old phraseology of legal documents referring to "medical and surgical staffs" is adequate in view of the development of special departments, especially since the establishment of the British College of Obstetricians and Gynæcologists

I am, Sir, yours faithfully,

C E A BEDWELL,
House Governor

King's College Hospital Denmark hill S E Jan 25th

OMENTOPEXY

To the Editor of THE LANCET

SIR,—In Mr O'Shaughnessy's admirable account of the surgical treatment of cardiac ischæmia, there is one point that deserves correction The author refers to the omentopexy of Rutherford Morison as an operation for cirrhosis of the liver and he comments on this matter as though that operation might be expected to influence favourably this obscure disease May I say that Drummond and Morison devised their operation not with the idea that it might cure cirrhosis, but as a method of dealing with the ascites, which may be such a distressing sequel of the changes in the liver? When used for this purpose alone, and in the circumstances which the authors of the operation indicated as being necessary to hold out a prospect of success, it has been most valuable

In showing its usefulness, may I be permitted to say that the patient to whom Mr O'Shaughnessy referred and on whom I operated—and who is now well thirty years after the operation—was rapidly going downhill at the time of the intervention He was accustomed to be tapped every fortnight and as a rule 22 pints of fluid were removed. A year after the operation he underwent a further intervention for the radical cure of hernia and for many years afterwards he was to all intents and purposes perfectly well and able to follow the laborious occupation of a stoker in a gas works For some years now he has lived in retirement, but when I heard from him in November last he was still enjoying good health.

Experience of this operation extending over many years has emphasised, what Rutherford Morison originally pointed out, that if these patients are to remain well they must give up the use of alcohol. The successful cases with which I am familiar have always faithfully observed that rule

I am, Sir, yours faithfully,

London W Jan 25th G GREY TURNER.

RADIOGRAM AND RADIOGRAPH

To the Editor of THE LANCET

SIR —Your preference for the word *radiogram* in your supplement On writing for THE LANCET and your defence of it in the subsequent correspondence seem to me to be reasonable and logical. Radiologists are divided into two camps on this question but there are many who like myself feel the termination *-graph* for the verb and *gram* for the noun to be more comfortable In medical discussions I often hear confirmed champions of *the radiograph* unwittingly calling it *the radiogram* *Skiagram* has a slightly archaic flavour and has few friends nowadays, while *roentgenograph* and *roentgenogram* are too distinctively American to gain ready acceptance in this country I believe that an etymological purist would question the respectability of the entire tribe, so mixed is their parentage *Radiogram* is in this respect no worse than its relatives *Radiograph* as a verb we must retain an X ray technician is a *radiographer* there is a Society of Radiographers and *radiography* is the appointed work of its members I would strongly urge the retention of *radiogram* as the corresponding noun I would even ask that those who prefer it should not be asked to change it when contributing to a journal which happens to prefer *radiograph* as the noun. More than that I venture to hope that the Oxford Dictionary will accept it in the future for its use in medical literature is well established. One point should not be lost sight of—namely ease of pronunciation A simple trial will show that it is easier and slightly more euphonious to say *the radiogram shows* or *in the radiogram there is* than to say *the radiograph shows* or *in the radiograph there is*—a point to consider in reading or listening to a paper in which such phrases often recur The word is needed, and is probably more often used in this special sense than in the sense of a wireless message which is usually spoken of as a *wireless* or a *radio* in colloquial speech. *Radiogram* in medical literature has now passed its fortieth birthday and may be considered to have atoned, by forty years of useful work for its rather disreputable ancestry

I am, Sir yours faithfully

Jan 24th. RADIOGRAMMARIAN

A SURVEY OF DIETS

A FEW years ago Prof E P Cathcart F R S and Mrs A. M. T Murray published accounts of the amount and type of food eaten by 154 families at St. Andrews and by others at Cardiff and Reading The diets were then expressed for the most part in terms of protein fat and carbohydrate The figures of those investigations have now been tackled afresh and tabulated according to the actual articles of food. In a report just issued as a green book [1] these findings are given together with a comparison of the choice of food by families of similar economic standing in 1911 and 1933 a report on the diets of 100 women students and some observations on the proportion of food lost in cooking and waste.

To take the parts of the report in order the St Andrews families ranged from the professional classes to the unemployed and were classified into seven groups according to the wage earner's employment (or unemployment) The average weekly expenditure on food per man value ranged in the groups from 6*s* 2*d* to 18*s* 5*d* Part of the inquiry was repeated at another season As might be expected the amount of meat eaten varied with the money spent on food bread showed the opposite tendency fish and game classified together were consumed fairly uniformly except in the richest group cereals and legumes grouped together were eaten least by the two lowest expenditure groups and in fairly constant amounts by the rest The diets were also analysed for their content of calcium phosphorus and iron by using figures from Sherman's Tables and from Sir John Orr and the Rowett Institute With this method of reckoning, all groups were found to take more than the 0·68 g calcium considered to suffice The two poorest groups alone got less iron and phosphorus on average than is considered necessary

The 53 Cardiff families were drawn on the whole from the less well paid inhabitants their average expenditure on food a week per man value ranged from 6*s* 8½*d* to 12*s* Here the meat consumption varied with income the choice of kind of meat differed in some respects from that in St Andrews for instance notably fewer sausages were eaten

The 48 Reading families were on the whole poorer than the others considered Their average weekly expenditure on food a week per man value was 5*s* 2½*d* to 9*s* 4½*d* Here again the amount of meat and dairy produce eaten varied with income The average dietaries for each group of consumers in Cardiff and Reading were considered to contain more than the basal requirements of calcium phosphorus, and iron and in each district and in every group the amount of first-class protein was considered to be above the minimum required The average weekly consumption of milk in St Andrews Cardiff and Reading was respectively 4·08 1·80 and 3·3 pints per man many more of the Reading families were receiving free or cheap milk than in the other districts

The diets of the 12 Glasgow families in 1933 differed from the 23 recorded in 1911 in several respects margarine was not eaten in the 1911 investigation while 11 out of 12 of the families of the 1933 group ate it. All the families bought white bread but whereas none before the war bought brown a quarter of the 1933 group did so The consumption of oatmeal had greatly diminished since 1911 The consumption of roots had risen definitely and that of leafy vegetables still more (29 per cent); none of the 1911 families and three quarters of the 1933 group had eaten fresh fruit the 1911 families took on average about 3 pints of fresh milk per man per week the 1933 about 2·5 pints; in both lots some families bought milk in other forms: 7 out of 23 bought buttermilk in 1911 and only 1 in 1933 5 of the first group bought condensed milk and 7 of the second

At the College of Domestic Science in Glasgow 100 women students ate meals of their own choosing and noted down afterwards the quantities they had taken for from three to five days The students were weighed and measured, and examined by a doctor and a dentist Their average height was 162·1 cm slightly more than the 159 2 cm used in the British Medical Association report , their average weight was 55 85 kg (B M A figure, 55 8 kg) Their average calorie intake was 2035 calories a day , this figure, the report points out, is in keeping with the 2400 calories laid down by the League of Nations committee, if the needs of a woman are accepted as 0 83 *of a man's* The average amount of protein taken was 76 10 g , of which 58 5 per cent was first class protein, a high proportion As the report says, the League committee laid down no level of fat requirement because it is so variable , the average fat consumption of the students, 79 01 g a day, is therefore compared with the average for the St Andrews diets, 118 6 g The average calcium intake (0 69 g) was very close to the figure 0 68 g considered by Sherman to afford a margin of safety, but the intakes varied widely

---

[1] A Dietary Survey in terms of the Actual Foodstuffs Consumed By E P Cathcart and A M T Murray Spec Rep Ser med Res. Coun., Lond No 218 London H M Stationery Office 1937 Pp 56 1s.

The estimation of losses incurred in preparing and cooking food and in its residue were made by two means large numbers of samples were tested out at the College of Domestic Science and the waste portions expressed as percentage of the weight of the articles purchased , here, of course, bones counted in heavily and the waste varied from none to 37 8 per cent In the other series of estimations the actual loss was calculated from the refuse pails of the St Andrews surveys and expressed as a percentage of the total calorie value The authors explain that here the losses could only be calculated on edible waste arising from vegetables, bread, and so on , they could not be calculated on bones, ham or bacon rind, for instance The mean percentage loss of edible calories was 2 7 and 2 6 for two series These figures, even if doubled, the report says, " make it very clear that in these St Andrews families at least the conventional 10 per cent for refuse and waste far overstates the real position If these families can be taken as representative then an allowance of 5 per cent for the loss of edible calories in a mixed diet allows an ample margin of error "

The authors conclude that the surveys cover a very representative sample of the population and that few of the diets could be regarded as really poor, far less hopelessly inadequate in energy, protein, and fat content, first class protein, and mineral salts At the same time the content of protective foodstuffs like milk green food, and milk of many diets left much to be desired The amount of tinned or prepared food bought was not large Speaking of a method of improving the dietary standard, they quote Burnet and Aykroyd saying " There is no reason to doubt that valuable results can be obtained, even among families with very small incomes, by educational means " "This," they add, " is not to say that lack of means plays no part Some at least of the families would have spent more on food if the money had been available But even so a large percentage would tend to purchase items of a luxury rather than those of an essential type The main causal factor of inadequate diets in many households is ignorance of how to buy, what to buy and how to use to the best advantage the material bought Balance of expenditure is an art unknown or ignored by many " The authors go on to point out some of the difficulties which hinder the diffusion of knowledge of dietetics and express the opinion that such teaching can only be sure of reaching the housewives if brought by personal contact, demonstrations with utensils which the wives can get too, and patient talk

IRELAND

(FROM OUR OWN CORRESPONDENT)

SOCIAL SERVICES IN THE IRISH FREE STATE

Mr Sean T O'Kelly, Minister for Local Government and Public Health in the Irish Free State, in a speech made in Cork last week reviewed the present condition of the various social services under the control of his department Speaking about national health insurance, he said that there was every indication that with the unification of the approved societies administration will be greatly improved. The membership of the society is increasing yearly, and is now over 500,000 The policy of his department and of the society is to ensure that the provisions of the National Health Insurance Act, 1933, are fully complied with , that all contributions legally due will be paid , and that every insured person will receive promptly the benefit to which he is entitled , and, on the other hand, to preserve the funds, which belong to the insured persons themselves, from depletion by dishonest claims Under the Widows and Orphans Pension Act, pensions amounting to £265,000 a year are being paid at present for 14,360 widows and 14,700 children, including orphans Under a new Bill already introduced the scope of the scheme will be considerably extended, for it will provide for all necessitous widows with dependent children, and the qualifying age for childless widows will be reduced from 60 to 55

While a substantial sum is held by the Hospitals Trust Fund, Mr O'Kelly said that it is to be used for endowment and also for projects now in the preliminary stages that eventually would require heavy expenditure on building and equipment There is a danger, he added, that with large sums available institutions might be erected without consideration of how much it will cost to maintain them, but it is not intended to multiply institutions and burden the ratepayers with heavy expenses merely because there is money for their erection

An investigation in selected areas has begun to ascertain the incidence of mental deficiency and epilepsy in the community This investigation, which is an essential preliminary to legislation, may take some time to complete, but will result, he hoped, in better provision for these unfortunate classes

Among the new services that are yearly increasing in importance are the maternity and child welfare and the school medical services There are still, however, a few counties where, owing to the absence of county medical officers of health, the medical inspection of school children has not yet begun In 1935 the number of children in the country medically examined exceeded 90,000 Under all schemes facilities have been provided for treating the defects discovered, and there are very definite indications of the improvement in the physical condition and health of the children Full advantage ought to be taken of the opportunities during their school life to correct as far as possible physical defects, and to give the children a healthy start in life About 24 000 children are being fed daily and every opportunity is being taken to urge the value of a milk ration of good quality and the necessity of ensuring the purity of the milk supplied

In 1932, the Minister concluded, the programme of the Government was for 75,000 houses to be built in a period of ten years, and the 35,000 mark has now been passed

OBITUARY

HAROLD WATERLOW WILTSHIRE D S O

M D Camb F R C P Lond

Harold Waterlow Wiltshire born in 1870 was educated at Cheltenham and Clare College, Cambridge where he went in 1897 He was always keen on sports and having gone into residence at Clare he took up rowing perhaps giving more time to that pastime than was quite consistent with his early medical studies The master of his college reminded him that he came to Cambridge to read and not to row Enough! he settled down to study and quickly passed his second M.B and graduated B.A in 1900 In 1901 he entered the medical school of King's College Hospital where his uncle, Dr (later Sir) David Ferrier was the senior physician He immediately put his whole energy into the work of the hospital and the social life of the school. He joined the hospital medical society and attended the meetings regularly He was a keen lawn tennis player and was chiefly instrumental in resuscitating the hospital lawn tennis club He became a member of the Hospital VI which won the inter hospitals junior tennis cup in 1909 and in later years he frequently captained the honorary staff VI which played against the Students VI He took a leading part in the formation of King's College Hospital Clubs and Societies Union which was founded in 1908

Wiltshire held the junior hospital appointments at King's so successfully and became such an accomplished and attractive teacher of clinical medicine that in 1910 he was invited to become assistant physician He regularly drew large numbers of students to his out patient department, and amongst his colleagues the students and the nursing staff he soon became the most popular man in the hospital.

When the European War broke out in 1914 Wiltshire immediately joined up he was gazetted captain in the R.A.M.C and served in France In 1916 he became temporary major and was transferred to Salonika. He was three times mentioned in despatches and for his distinguished war service he was awarded the D S O in 1918 the O B E in 1919 and the Order of St. Sava of Serbia.

In 1919 when new departments were created in the medical school of King's Wiltshire was immediately chosen director of the cardiological department he was also appointed vice dean and when The Platanes the hall of residence for students on Champion Hill had been reorganised he was appointed the new warden in charge He had been elected president of the Listerian Society in 1914 but in consequence of the war no meetings were held he was however again elected president in 1919

In 1922 Wiltshire relinquished private practice in order to devote his time to teaching and administration He remained physician to the hospital but combined clinical teaching with the lectureship and demonstratorship of morbid anatomy so that clinical teaching then became linked up with post mortem findings In 1924 however to the profound regret of his colleagues at King's, he was compelled through serious illness to relinquish some of his teaching appointments; unfortunately his health became steadily worse so that in 1925 he felt compelled to resign his office at King's; he was immediately appointed consulting physician to the hospital.

He married Miss Ellen Tibbit daughter of the late Edward Tibbits M D of Bradford and then retired to Bembridge, Isle of Wight. His wife had been a former sister at King's College Hospital and with devoted care she nursed him back to reasonable health, so that he was able to enjoy some of the peace and quiet of country life. He soon became an enthusiastic and successful gardener

Unfortunately his wife herself became seriously ill in the early part of 1933 and he then nursed her with tender devotion but after some months she died of an incurable illness Her death was a sad blow to Wiltshire and from it he never really recovered. His health began to fail rapidly and he became very ill in July last He realised exactly what was happening but he bore his final illness with inexhaustible patience and fortitude He died on Monday Jan 18th.

Harold Wiltshire always gave of his best whether treating a patient, teaching a student or playing a game—he never spared himself and by his death there has passed on a brave gentleman a good and sincere friend a charming companion and a loyal colleague

H WILLOUGHBY LYLE

WILLIAM VERNON SHAW O.B E M D Oxon

MEDICAL OFFICER, MINISTRY OF HEALTH

WE regret to record the death on Jan 21st of Dr W Vernon Shaw Born in 1874 the eldest son of a former rector of St John's Chelsea and subsequently of Callington Cornwall Dr Shaw was a graduate in arts and medicine of the University of Oxford and there and at St Mary's Hospital he had a brilliant career being Brackenbury exhibitioner at Balliol in 1891 and winning an open science scholarship at Christ Church a year later He took a first-class in Parts I and II of the Natural Science School, and was for some years a demonstrator in physiology on the University staff and tutor and lecturer at St John's College He gained an entrance scholarship at St Mary's Hospital and was Kerslake Scholar in 1899 After holding several house appointments at St. Mary's Hospital he was for some years in practice at Malton before being appointed to the staff of the National Health Insurance Commission in 1913 During the war he was engaged in mobilising the supply of drugs and medical stores for the Forces and civil population a position for which his training in organic chemistry eminently fitted him and for his services he was awarded the O B E. in 1920

Photograph by [illegible]

DR. SHAW

The following from a friend in the Ministry of Health is a general estimate by his colleagues of Dr Shaw's fine qualities

"Endowed with an alert mind and retentive memory, by wide reading and experience, Vernon Shaw had acquired a profound knowledge of clinical and preventive medicine Yet he was eminently practical, and his reputation as an epidemiologist 'in the field' was second to none, and it will secure for him an honourable place in the public health annals of our country He will be remembered gratefully by many medical officers of health for his diagnostic acumen in outbreaks of small pox His thorough and painstaking investigations into outbreaks of enteric fever and other infectious diseases in Gloucester, Chorley, Bolton on Dearne, Denby, Malton, and Eton are recorded in the official publications of the Ministry, and they will remain as classics for future students of epidemiology His strenuous and illuminating work during the recent epidemic of typhoid fever in Bournemouth and Poole was almost the last of his labours

"As a colleague, Shaw is unforgettable He was one of the good companions of official life, full of knowledge, and of such variety of knowledge, wisely used and freely shared, spending himself wholeheartedly—perhaps, at times, recklessly—in the sphere of duty to which he was devoted and in which he could exploit his flair for detection and his telescopic vision of distant clues Supple, as R L Stevenson has phrased it, in things immaterial, he held fast to a code of righteous conduct and though, to be sure, he was always ready and responsive in humour, no discussion, no conversation even, on professional matters could be anything but earnest for him, and he defended or demolished an opinion with parallels or divergents amplified with names, nicknames, dates, places, and ancillary circumstances poured from his astonishing memory Incompetence, assumption of learning, or maybe a tactless approach, might quickly fuse a vein of impatience in the rich metal of his character, but to honest poverty of ideas he was a gracious and generous benefactor Official reports give but the formal aspects of his life and work, a diary of his journeyings, experiences and contacts in war time and in peace, and of his own observations on some points in the clinical history of certain of the infectious diseases would have made interesting reading, but if ever he began one it is probable that, unleisured and unintrospective as he was, he would take leave of it without regret

"He was a staunch Churchman, and regularly read the lessons at his parish church He had numerous interests, his particular hobby was gardening, but no account of his career would be complete without reference to his skill as a driver of railway locomotives, and he treasured a letter of appreciation which he received from the London and North Eastern Railway for his services in that capacity during the general strike of 1926

"The death, 15 months ago, of his wife to whom he was much attached was a painful shock to him, and he seemed to seek the dubious anodyne of deeper application to work, now before his time he too has passed on. He leaves a family of one son and three daughters to whom sincerest sympathy is tendered."

Sir James Marchant, writing in the *Bournemouth Daily Echo* of Jan 22nd, says —

"In our recent outbreak Dr Shaw came to our boroughs immediately, and threw himself unreservedly into tracing the source of the disease, in checking its spread, and overwhelming it He brought to bear upon the outbreak all his special qualifications, and early and late he was to be seen going round our districts, visiting farms and dairies, examining those who were employed in any way in milk production and distribution, following up every clue and suggestion with indefatigable diligence, until the outbreak was under complete control. With all his accomplishments and experience he had the happy gift of working with medical officers of health and local committees wherever he went, and our own representatives have paid warm tribute to his humility, persuasiveness, and sterling character"

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

IN the House of Commons on Thursday, Jan. 21st, Wing-Commander JAMES gave notice that on the House going into Committee on the Civil Estimates he would call attention to the need for implementing the report of the Brock Committee on voluntary sterilisation and move a resolution.

Mr ROWSON gave notice on the same day that on the House going into Committee on the Civil Estimates he would call attention to the question of nutrition and move a resolution

In the House of Commons on Jan 25th the Unemployment Assistance (Temporary Provisions) (Amendment) Bill was read a second time

In the House of Commons on Jan. 26th Mr GROVES presented a petition signed by 19,515 citizens in this country asking Parliament to abolish the present powers for the vivisection of dogs

In the House of Lords on Jan 26th the Lord CHANCELLOR took his seat on the Woolsack on his return after several months' illness

Duties on Imported Liver Products

In the House of Commons on Jan 25th Sir REGINALD CLARRY asked the Government to offer the same exemption from duty to liver products that had been given to sweetbreads used in the preparation of insulin. Continental chemists could import the drugs with a duty of only 10 per cent, instead of the 20 per cent imposed by the Bill on the raw materials, about 800 tons of which had to be imported annually, only 20 per cent of this being available from our Dominions Under the tax the drugs would cost an extra 3½*d* per person per week.

Captain EUAN WALLACE, Secretary for the Overseas Trade Department, answered that the real difficulty was that it was impossible to trace the progress of liver after it came into this country

WEDNESDAY, JAN 20TH

Children and Objectionable Cinema Pictures

Mr DAY asked the Home Secretary whether he would give particulars of the result of consultations held between his office and the Secretary of State for Scotland on the exhibition at cinemas of objectionable pictures which were harmful to the minds of children and young persons, and what action he proposed taking in the matter —Mr GEOFFREY LLOYD, Under-Secretary, Home Office, replied The hon Member is no doubt referring to the consultations between the Home Office and the Scottish Office which took place as a result of representations from the National Cinema Enquiry Committee It was arranged that the two Departments should examine the questions raised by the deputation and in particular that a survey of the conditions in Scotland should be undertaken This has now been done and after careful consideration my right hon friend and my right hon friend the Secretary of State for Scotland have come to the conclusion that there are no sufficient grounds for the holding of a comprehensive enquiry such as the deputation suggested. It has however been decided to make certain changes in the composition and terms of reference of the Film Censorship Consultative Committee which was set up in 1931 and in particular to include representatives from Scotland The necessary steps are being taken and my right hon friend before long hopes to be in a position to make a further announcement on this subject

School children and Road Safety

Mr VIANT asked the Minister of Transport whether he had given consideration to the recommendations of the committee on the safety of school-children; and if it was his intention to apply the speed limit in the vicinity of schools in built up areas —Mr HORE BELISHA replied: Yes Sir and to the second part of the question wherever *the circumstances justify it*

THURSDAY JAN 21ST

Grants to Voluntary Hospitals in Special Areas

Mr DAY asked the Minister of Labour whether the commissioner for the special areas had made any grants to voluntary hospitals towards the alteration or extension of their buildings and if he would give particulars.—Mr ERNEST BROWN replied I would refer the hon Member to paras 247 and 248 and to Appendix XI of the Third Report of the Commissioner for Special Areas (England and Wales) Cmd 5303 which covers the period up to Sept 30th 1936 The following are brief particulars of schemes for assisting voluntary hospitals which have been approved since that date —

Organisation	Nature of work	Location of work	Estimated total cost of work
Sunderland Royal Infirmary	Construction of new out patients department, ward block, nurses' home and staff quarters.	Sunderland	£83 500
Blaina and District Hospital	Additions to surgeon's room and mortuary provision of ultra violet ray and other equipment and new motor ambulance.	Blaina	£574
Rhymney Cottage Hospital	Provision of new X ray room nurses bedroom new ambulance and other equipment	Rhymney	£2 06

Distressed Areas and the Means Test

Mr THOMAS WILLIAMS asked the Minister of Labour if he had yet considered the suggestions made by the Birmingham association for the relief of distressed areas regarding modifications of the means test; and if so if he would state the result —Mr ERNEST BROWN replied: I am informed by the Unemployment Assistance Board with whom I have been in consultation in this matter that while their legal powers do not enable them to act precisely in the manner suggested by the association the Board are fully in sympathy with the desire of the association to remove difficulties due to temporary unemployment affecting families or individuals who have transferred from depressed areas They recognise that household expenses in the new district may for some time after removal be greater than they were in the old and further that the removal may result in the creation of special needs Under the new regulations there is also power which will be exercised to meet any reasonable increase in rent which may result from removal For these reasons it is felt that there should be no apprehension that the position of a household removing to a more prosperous area will be rendered difficult and the Board suggest that any person in receipt of an unemployment allowance who contemplates removal should see the Board's local officer in order that the details of his case may be considered and information afforded as to what his probable position will be in the new area

Thefts of Dangerous Drugs from Doctors Cars

Mr RHYS DAVIES asked the Home Secretary whether he proposed to take any action to prevent the recurrence of cases in which members of the medical profession had had dangerous drugs stolen from their motor-cars —Sir J SIMON replied No Sir I have no grounds for thinking that these thefts are other than ordinary cases of petty larceny and I do not think there is any action I can usefully take in the matter

Mr DAVIES: Does not the right hon gentleman think that some responsibility ought to be placed upon the medical profession for neglecting to take care of these dangerous drugs?

Sir J SIMON: I think that the remedy here is the exercise of care by the individual who has such a package in his charge When we consider what a large number of people are moving about—skilled doctors who are attending medical cases—very many of whom have something of the sort with them I do not know that the number of cases is very surprising.

Scarlet Fever in Doncaster

Mr SHORT asked the Minister of Health whether he could make any statement respecting the recent outbreak of scarlet fever in Doncaster and area; whether any proof had been obtained as to whether the outbreak was due to a polluted milk-supply; and if so what steps were being taken to prevent similar outbreaks in the future —Sir KINGSLEY WOOD replied: Some 160 cases of scarlet fever occurred in Doncaster and the adjoining rural district in the recent outbreak, together with a considerable number of cases of sore throat I am advised that the outbreak was due to the infection of milk from one farm When the particular milk-supply had been identified as the source of infection arrangements were made for the pasteurisation of all milk coming from that source As regards the general question I cannot add anything at present to the answer I gave on this subject on Nov 12th

Mr SHORT: Will the milk producer be prosecuted in this case?

Mr MACLAREN: No he will get a subsidy (Laughter)

Small-pox at Oldham

Mr GROVES asked the Minister of Health on what day the first case of small pox was discovered at Oldham; for how long had the patient been infected before discovery and how many cases had been notified —Sir KINGSLEY WOOD replied: The first case was notified on Nov 27th 1936 I am advised that this patient was probably infected about 23 days earlier which interval includes the period of incubation when there are no clinical manifestations Nine cases in all have been notified

Accommodation of Ministry of Health Staff

Lieut -Commander FLETCHER asked the Minister of Health if he was satisfied regarding the accommodation of the staff at the Ministry; how many of the staff worked in the basement rooms and for what periods of time; if there was overcrowding in any of the rooms if all rooms occupied by staff had direct communication with the air if any of the rooms necessitated the use of artificial light throughout the working day and what representations regarding the office accommodation had been received from the staff associations —Sir KINGSLEY WOOD replied I have from time to time received representations from the Departmental Whitley Council about the accommodation provided for the staff of my Department All such representations are carefully considered and where necessary brought to the notice of the Office of Works In general the accommodation in the Ministry is satisfactory About 50 to 55 clerks spend a normal working day of about six hours for three months at a time in the basement courts which are large light and well ventilated rooms. About 20 other clerks work in a basement court about one hour every morning There is no overcrowding in any part of my Department, the only staff rooms not in direct communication with the open air are five messenger boxes Natural lighting in the rooms is generally good and in only a very small proportion of cases is it necessary for any officer to resort to artificial light all day under normal weather conditions

Health Insurance Medical Fees for Young Persons

Mr **Rhys Davies** asked the Minister of Health whether he had now been able to secure agreement with the medical profession in relation to the fees to be paid in respect of young persons entering into employment for the first time, and, if so, if he would state the nature of that agreement —Sir **Kingsley Wood** replied I am still in communication with representatives of the medical profession on this matter and I am not yet in a position to make a statement

FRIDAY, JAN 22ND

Ophthalmic Benefit in Scotland

Mr **Henderson Stewart** asked the Secretary of State for Scotland if he was aware that dissatisfaction was felt by optical practitioners in Scotland at the omission from the new draft regulations for ophthalmic benefit of due recognition of the services of sight testing opticians, and whether, in view of the proved service of these practitioners, he would state the reason for amending, in this respect, the regulations of 1922 —Mr **Elliot** replied I have received certain representations from opticians regarding the terms of the draft regulations referred to and I have arranged to receive a deputation from Scottish opticians on this subject on the 25th instant The views of the opticians will receive the careful consideration of my right hon friend the Minister of Health and myself before the terms of the substantive regulations are finally decided on

MONDAY, JAN 25TH

Blind Persons

Mr **Messer** asked the Minister of Health how many blind persons were registered in England and Wales, how many were in receipt of the blind pension, how many receiving augmentation-of income grants from local authorities, and how many above the age of 16 were unemployable —Mr **Hudson** replied On March 31st, 1936 (the latest date for which figures are available) there were 67,534 registered blind persons in England and Wales, and of these 22,415 between the ages of 50 and 70 were receiving an old age pension on account of blindness, while 54,675 over the age of 16 were classified as unemployable I have no information as to the actual number of blind persons who are in receipt of financial assistance from the local authorities

League and Health Organisation in Spain

Miss **Rathbone** asked the Secretary of State for Foreign Affairs whether his attention had been called to the report of the health organisation of the League that 200 motor-omnibuses were needed for the Spanish Government to assist in the evacuation of the civilian population of Madrid, and whether he could assure the House that the Spanish Government would receive every facility for obtaining these motors, if they desired to do so, from this country —Viscount **Cranborne**, Under Secretary for Foreign Affairs, replied I understand that the report of the health experts sent by the Secretary General of the League to Spain at the request of the Spanish Government has been placed on the agenda of the present session of the Council, but that it has not yet been considered by the Council As regards the second part of the question, I can assure the hon lady that no difficulty will be placed in the way of the purchase of omnibuses for this purpose

Cure for Neuro-lymphomatosis

Mr **Hall-Caine** asked the Minister of Agriculture whether his attention had been called to the recently announced discovery by the university of British Columbia of a cure for neuro lymphomatosis, which caused a loss of £4 000,000 to the poultry industry in Great Britain last year, and whether any action was to be taken in the matter —Mr **Morrison** replied I have seen the brief announcement relating to this discovery that appeared a short time ago in the press As regards the second part of the question, we must, I think, await the full account of the work on which the claim is based

Milk Supply in Schools

Mr **Ellis Smith** asked the President of the Board of Education the percentage of school children who received milk in the schools during 1935 and 1936 in the following places, London, Glasgow, Salford, Stoke on Trent, Eastbourne, Hastings, and Bournemouth —Mr **Oliver Stanley** gave the following answer with regard to English areas —

A = Percentage* of children receiving milk under the Milk in Schools Scheme

B = Percentage* of children receiving milk outside the Milk in Schools Scheme

C = Total percentage* of children receiving milk

Area	October 1935			October 1936		
	A	B	C	A	B	C
London	63 6	0 2	63 8	62 6	0 4	63·0
Salford	46 9	6 9	53 8	44 5	6 6	51 1
Stoke on Trent	48 1	1·0	49 1	51 3	0 8	52 1
Eastbourne	40 0	—	40 0	45 8	—	45·8
Hastings	30 3	2·2	32 5	32 6	2 5	35 1
Bournemouth	48 3	—	48 3	30 8	0 7	31 5

* Percentage = Percentage of number on registers

Coroner and Press Persecution

Sir **William Davison** asked the Home Secretary whether his attention had been drawn to the remarks of the coroner in the case of a recent inquest as to the persecution by representatives of the Press in this and other cases of the relatives of people who died under such circumstances, and whether any steps could be taken by the Government for the protection of citizens from Press persecution of the kind mentioned —Sir **John Simon** replied The coroner in the case referred to observed that all decent people must sympathise with the relatives in the distress which was caused to the bereaved family by the way in which they were persecuted by such inquiries and I must say that I agree with the coroner I hope very much that the responsible heads of the press may devise a means of preventing the repetition of such incidents by sternly discouraging such mistaken and heartless enterprise I am proposing to communicate with the Newspaper Proprietors Association and the Newspaper Society on the subject

TUESDAY, JAN 26TH

Safety in Mines

Miss **Ward** asked the Secretary for Mines how many colliery companies employed fully certified mine managers as safety officials, and how many companies issued free safety helmets to their men —Captain **Crookshank** replied In November last there were about 40 mines or groups of mines where special safety officers had been appointed, additional to the manager and other safety officers required by law I do not know how many of these safety officers held managers' certificates The arrangements between the owners and the workmen for meeting the cost of the safety helmets now widely used vary considerably There is no settled practice and I have not got the information asked for in the second part of the question

Health Insurance Ophthalmic Regulations

Captain **Macnamara** asked the Minister of Health whether he was aware of the anxiety amongst opticians of the country at the new draft regulations concerning the payment of their services for ophthalmic treatment and whether he would give an assurance that their position would be regularised in the new regulations so that there would be no doubt about the legality of their claim for service fees in the future —Mr **Hudson**, Parliamentary Secretary to the Ministry of Health replied There has never been any intention of depriving opticians of a fee for services rendered by them in connexion with the supply of glasses to insured persons but my right hon friend is aware that some doubt has been expressed as to the position under the proposed regulations The matter is receiving the careful consideration of my right hon friend and of the Secretary of State for Scotland and if they are satisfied that some modification of the wording of the draft regulations is required in order to legalise the payment of such a fee the necessary modification will be embodied in the substantive regulations

Bakehouses and Factory Regulations

Mr **Viant** asked the Minister of Health whether his attention had been directed to the impossibility of local authorities being able to prosecute for the purpose of enforcing Section 99 of the Factory and Workshop Act 1901 authority for such having previously been that of the Home Secretary but transferred by the Factories and Workshops (Transfer of Powers) Order 1921; and if so was it his intention to introduce amending legislation at an early date.—Mr **Hudson** replied My right hon friend is aware of the lack of powers referred to by the hon member and my right hon friend the Home Secretary has under consideration the question of dealing with the matter in the forthcoming Factories Bill.

PUBLIC HEALTH

WHAT CHILDREN DIE OF

Between 1861–70 and 1921–30 the standardised death rate of England and Wales declined from 21·3 to 10·6 per 1000 inhabitants in other words mortality in recent years is but half what it was sixty to seventy years ago To this reduction the ages of early childhood have made a large contribution. A study of the decline included in the Annual Report of the Chief Medical Officer of the Ministry of Health for 1933 shows that at each year of age between 1 and 5 the death rate in 1930–32 was a little *less than a quarter of the corresponding* rate in 1861–70 This improvement still continues In the most recent years for which figures are available, 1933–35 the death rate at ages 1–5 years is only approximately 40 per cent of the level in the years immediately preceding the war and even as much as one third below the rate of the decade 1921–30 A corresponding but less phenomenal improvement is shown at the later ages of childhood

ROOM FOR IMPROVEMENT

Satisfactory as is this trend and the evidence it gives of a higher standard of health at a most important—perhaps *the* most important—stage of life we must not let it make us complacent or blind us to the fact that there is still ample room for further improvement The Registrar General's Text volume for 1934[1] includes a comparison of mortality in England and Wales with that recorded in a number of other countries One of the most striking contrasts is to be seen in early childhood Mortality in this country in 1930–32 at ages 1–5 was less than half the rate in Hungary and Italy and less than a third of that in Portugal on the other hand it was more than double the mortality rate of Norway nearly double the rate in Sweden and some 50 per cent above the rates of Holland and Germany Even within England and Wales wide differences at these ages are apparent In 1934 the county boroughs had a rate nearly 20 per cent above that of the country as a whole while in the rural districts it was 25 per cent below The counties of Durham and Northumberland have childhood rates nearly 50 per cent above the national level while in the south western division comprising the counties of Cornwall Devonshire Dorsetshire Somersetshire and Wiltshire they are one third below that level Internationally and internally there is no reason to remain content with the advance that has already so successfully been made How that advance can be most easily extended may perhaps be clarified by a study of the main causes of death in childhood. The Registrar General's returns provide the necessary data. The medical tables for 1935 the latest issued show that that year was particularly favourable to child life the mortality rates being below any previously recorded But owing to the epidemicity of the common infectious diseases figures for a group of years are more satisfactory material than those of a single year We may take those of the last quinquennium 1931–35 as our index In those five years nearly 77 000 deaths were recorded at ages 1–5 a mortality rate of 6·6 per 1000 children 31 000 at ages 5–9 a rate of 2·2 per 1000 and 24 000 at ages 10–14 a rate of 1·4 per 1000

THE VARIOUS CONTRIBUTORS

At ages 1–5 the largest contributor was *pneumonia* which in all its forms accounted for slightly more than one quarter of all the deaths or a mortality rate of 1·7 per 1000 The great majority of these deaths are certified as broncho pneumonia Next on the list comes the most ubiquitous of the infectious diseases of childhood measles In 1931–35 it was given as the cause of death of 9305 children at ages 1–5 or 12·2 per cent of the total deaths at these ages At ages 5–9 it was responsible for a further 1304 deaths or 4 per cent of the total at later ages its contribution becomes negligible Over 10 000 deaths from measles in five years at ages 1–9 is a clear indication of the field in which convalescent and adult serum can operate

A similar assessment can be made of the maximum advantage in terms of mortality that artificial immunisation against *diphtheria* might bring about In 1931–35 the number of deaths attributed to diphtheria was 5400 at ages 1–5 (7·1 per cent. of the total deaths and a death rate of 408 per million) 6589 at ages 5–9 (19·4 per cent. of the total deaths and a death rate of 421 per million) and 1741 at ages 10–14 (7·3 per cent of the total deaths and a death rate of 102 per million), a total of nearly 14 000 deaths in five years at ages 1–14 Its relative importance at ages 5–9 is particularly striking in *these five years diphtheria was the cause of nearly* 1 death in every 5 No efforts to lower the general mortality rate at these ages can ignore that *fact* *Whooping-cough* is a serious cause of mortality at the youngest ages 1–5 but not thereafter at ages 1–5 it was directly responsible in the years of review for 5022 deaths or 7·3 per cent. of the total mortality

Two other causes stand out at each of the age groups—namely *non respiratory tuberculosis* and *violence* To the former was attributed between 8 and 9 per cent of the total mortality at each age (a total of some 11 000 deaths at ages 1–14) From the latter the annual average number of deaths was *a little over 1000 at ages 1–5 (with roughly 3 males* to 2 females) nearly 900 at ages 5–9 (2 males to 1 female) and some 500 at ages 10–14 (3 males to 1 female) Put proportionately roughly 1 death *in 15 at ages 1–5 1 in 8 at 5–9 and 1 in 9 at* 10–14 was due to violence of one kind or another The causes naturally change with increasing age In the youngest age-group the highest contribution is made by burns and scalds closely followed by deaths from falls and crushing (a heading which includes road accidents), at the later ages burns become relatively few, drowning comes into greater prominence, but some two-thirds of the deaths are debited to falls and crushing. Improvement in this category is, therefore, very much a problem of the roads, and for that, unfortunately, there appears to be no easy or immediate solution. Deaths due to burns have declined substantially in the last quarter of a century.

---

[1] See *Lancet* 1936 2 12 5

The epidemic diseases of the central nervous system make a relatively small contribution and fluctuate considerably from year to year. In 1931–35 the average annual quota at ages 1–14 was 88 deaths from *poliomyelitis* (acute and polio encephalitis), 75 from *encephalitis lethargica*, and 434 from *cerebro-spinal fever*. The 2171 deaths from the last, the product of the epidemic rise and fall in this disease since 1929, are but little below the deaths due to *scarlet fever*—viz., 2589 deaths. In 1931–35 the notifications of the former (at all ages) were 7850, of the latter they numbered more than half a million, a striking contrast in relative fatality.

Respiratory tuberculosis appears as a cause of death at each age but not prominently before the group 10–14 years, in which it caused approximately one-thirteenth of all the deaths. Its continual decline both in childhood and adult life holds out hopes of a considerable improvement in this figure. Other causes that become of numerical importance in these later years of childhood are *heart diseases* (10·4 per cent. of all deaths), *rheumatic fever* (4·7 per cent.), and *appendicitis* (4·6 per cent.). To the last named were attributed in this five years close on 3000 deaths at ages 1–14, and it is reasonable to suppose that a proportion of these might be averted. Other diseases of the *digestive* system have their peak in early life and decline as childhood advances. A final cause of death of no small importance at each age is disease of the *ear* and *mastoid sinus* to which in these years of childhood between 500 and 600 deaths were annually attributed.

THE WORST OFFENDERS

Ignoring these and many other relatively minor causes of death, this brief review of what children die of in England and Wales brings us to the following answers. At ages 1–5 the most prominent causes of death in recent years have been (in order of their importance) pneumonia, measles, non-respiratory tuberculosis, whooping-cough, diphtheria, and violence; together they accounted in 1931–35 for just over two-thirds of the total mortality rate at these early ages. At ages 5–9 the most important components are diphtheria, violence, pneumonia, and non-respiratory tuberculosis, accounting for half the total mortality. At ages 10–14 we have in order of merit, or rather demerit, violence, heart disease, non-respiratory tuberculosis, respiratory tuberculosis, diphtheria, and pneumonia, accounting in all for just over half the total mortality.

Diphtheria, pneumonia, violence, and non-respiratory tuberculosis appear, it will be noted, in each of the three age-groups and contribute, approximately, one-half the total mortality at 1–5 and 5–9 and one-third at 10–14. Clearly under these four headings must lie a good share of the possible improvement in our mortality rates in early childhood.

Maternity in Willesden

A MAJOR difficulty in the study of maternal mortality is to obtain series of confinements which are sufficiently large, sufficiently homogeneous, and comparable one with another. The expected mortality is only about 4 per 1000, and hence it is only in series of at least 10,000 confinements that fluctuations in the mortality rate due to chance alone are not likely to be very considerable. Such a series is rarely comparable throughout. Changes in the type of patient included, in methods adopted and in record keeping may each make it impossible to generalise about any one series, and when a comparison of one group with another is required the difficulties in finding comparable series are very great. The women in every group, whether attended by doctors, by midwives, or at institutions, are in some way selected, and only the puerperal mortality rate as recorded by the Registrar-General, which must by definition include all the deaths certified as due to natural causes, based on all the births, is free from these objections. Even here we must be chary of our conclusions since, apart from the effects of chance, the incidence of morbidity may vary between different areas; the incidence of the toxæmias, for example, is believed to be higher in the north and west of England than in London and the south-east.

Comparisons, therefore, in maternal mortality rates are not only odious; they are fallacious. Nevertheless the puerperal rate recorded by the Willesden public health department for the first 3000 women confined in their maternity hospital does at least merit attention and further inquiry.[1] Of the total, 2939 were "booked" cases and showed a puerperal mortality rate of 1·02 per 1000 (live and still) births, while 61 were admitted as emergencies, with a mortality rate of 65·57, so that the rate for the whole series was 2·33. The women were unselected in the sense that none were refused admission or transferred elsewhere (except a number of normal cases who could not be admitted owing to pressure on beds) and having regard to the large number of abnormalities and to the extremely high proportion of primiparæ (1454 primiparæ to 1546 multiparæ), these rates are very satisfactory. If the women admitted as emergencies and the 4 deaths among them are taken out of the hospital's series and included in the remaining 11,213 births and 44 deaths respectively, which occurred in the borough during the years in question, a puerperal mortality rate over the period for the rest of the borough of 4·26 is obtained. This latter rate presumably contains a certain number of deaths from abortion and other deaths early in pregnancy; such women would not in any case have come under the care of the maternity hospital and the implied argument is somewhat weakened thereby; but even so the deduction can fairly be made that in Willesden the chances of a safe confinement are greater, as a whole, for a woman who is confined as a booked case at the maternity hospital than for one who is confined elsewhere.

The report does not give details of the borough council's maternity organisation or of the particular methods in use by Mr. Arnold Walker at the maternity hospital. It will be recalled that on the advice of the medical officer of health, Dr. G. F. Buchan, the council some years ago placed an experienced consultant obstetrician in direct clinical charge of their whole maternity organisation, including the maternity hospital, and this is the main feature of their scheme. This far-sighted policy is now, it seems, being justified by its results.

---

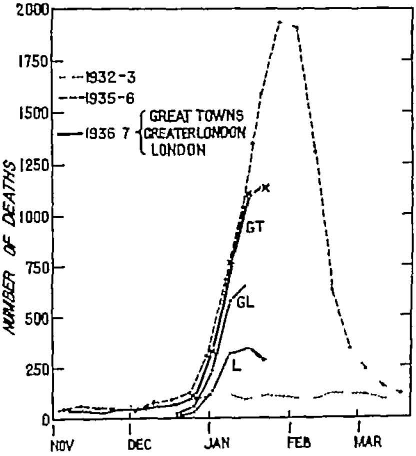
Influenza

Last week 1130 deaths were attributed to influenza in England and Wales The number is only 30 more than those reported in the previous week and it is now evident that the epidemic is on the wane and will not reach the peak of 1932–33 This can be seen on the graph which has been brought up to last Saturday and on it now is traced the course of the epidemic in London and in the Greater London which includes 26 towns in the Outer Ring Here it may be noted how large a share of the mortality was at first taken by Greater London but that the epidemic began to abate there while it was still extending in more distant parts of the country Last week in London itself the deaths had dropped sharply from 344 to 273 Those who wish to trace the probable course of the curve for the Great Towns during the next week or two may note that the ratio of deaths since the beginning of the year has diminished week by week in the following scale: 3·4 2·4 1·4 and now 0·97



Graph showing total deaths from influenza in the Great Towns on the last day of each week in three different years.

It is generally agreed that the character of the disease has changed but little during the epidemic and certainly not in the direction of becoming more virulent This is evident from the age distribution of the 1100 deaths in the week ending Jan 16th There is no sign here whatever of the shift of mortality to the younger ages which is the now familiar danger signal.

Ages	Deaths	Percentage of total
0–24	71	6·5
25–44	111	10·1
45–64	380	34
65 and over	538	48·9
All	1100	100·0

Admissions to L.C C hospitals have we learn fallen right off There is still some pneumonia among the older people but the notifications of pneumonia in London dropped from 440 to 326 In the previous week 2823 cases of pneumonia were reported throughout the country as against 2338 the increase being mostly in Yorkshire and the north western area. This tendency does not seem to have extended further north. Pneumonia has been little mentioned in Edinburgh and still less in Northumbria the distribution has been patchy and often neighbouring communities have suffered very unevenly Most distress has been felt in the Yorkshire wolds and the Scottish islands where wind and rain have contributed. In Ireland while there have been more cases the type has remained definitely mild there is in fact no abnormal pressure on Dublin hospitals for this time of year It has been said with some truth that all over the British Isles the medical profession has been busier than it was during other equivalent epidemics because of the greater readiness of the public to call for their help; the habit has been variously described as valetudinarian or sensible

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 16TH 1937

Notifications—The following cases of infectious disease were notified during the week: Small pox 2 (Failsworth U.D Lancs); scarlet fever 1513; diphtheria 1186 enteric fever 57; pneumonia (primary or influenzal) 2823; puerperal fever 40; puerperal pyrexia 140 cerebro-spinal fever 42 acute poliomyelitis, 5 acute polio-encephalitis 1 encephalitis lethargica 9; relapsing fever 1 (Kendal); continued fever 1 (Poplar); dysentery 23 ophthalmia neonatorum 78

The number of cases in the *Infectious Hospitals of the London* County Council on Jan 22nd was 3857 which included: Scarlet fever 898; diphtheria 1031; measles 16 whooping cough 552; puerperal fever 10 mothers (plus 5 babies) encephalitis lethargica 84 poliomyelitis, 2 At St Margaret's Hospital there were 14 babies (plus 6 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns including London there was no death from small pox or enteric fever 11 (0) from measles 7 (2) from scarlet fever 20 (7) from whooping-cough, 42 (8) from diphtheria 41 (9) from diarrhoea and enteritis under two years and 1100 (311) from influenza. The figures in parentheses are those for London itself

Oxford reported 3 deaths from measles Stoke-on-Trent and Swansea each 2 The whooping-cough deaths were widely scattered in ones and twos over 19 great towns outside London Fatal cases of diphtheria were reported from 24 great towns Liverpool 7 Hull 5 Manchester 4 Birmingham 3

The number of stillbirths notified during the week was 207 (corresponding to a rate of 42 per 1000 total births) including 10 in London.

Guy's Hospital Medical School.—An important extension is now being built at Guy's which will centralise the whole medical school in one block of buildings with easy access between the various departments In the new building a large and modern pathological department with plenty of accommodation for research &c will be provided the departments of pathology bacteriology and clinical chemistry will be housed under one roof there will be adequate accommodation for the medical research unit and clinical research fellow and also for the pharmacological department while the physics department will be made large enough to prevent the necessity of the duplicating of classes Other improvements will be an extension of the research accommodation available in the physiological department an additional demonstrator's laboratory and an extension to the [illegible] meeting room and a staff common room. The removal of the physics department from the existing buildings will enable better accommodation to be found in the school for operative surgery and for X ray living anatomy and human physiology

MEDICAL NEWS

University of Oxford

On Jan 21st the degree of doctor of medicine was conferred on F W Brown and of bachelor of medicine on A H M Richards Dr A E Barclay was incorporated as D M from Christ's College, Cambridge

An election to the Philip Walker studentship in pathology will be made shortly

The studentship is tenable for three years and may be extended for another two It carries a stipend of between £300 and £350 and the student will be expected to devote his full time to pathological research though he may hold a demonstratorship in the department of pathology Applications should be sent to the registrar not later than April 24th Further details will be found in our advertisement columns

University of Cambridge

On Jan 28th the following degrees were conferred —

M B B Chir—D A. S Blair R F Jarrett R Kauntze, and J Wilson

M B—*R B Davis and A G Salaman

B Chir—A M Barry F G A Beckett *H C Maclaren C McNeill *K M Mayall H K Moller *A M M Payne *K W B Rostron and O N Roussel

* By proxy

University of London

The title of reader in physiology in the University has been conferred on Dr W H Newton in respect of the post held by him at University College

The Geoffrey Duveen travelling studentship in otorhinolaryngology has been awarded to Mr P G Scott, chief assistant to the ear department of St Bartholomew's Hospital

University of Edinburgh

The Cameron prize for 1937 has been awarded to Dr J B Collip, F R S, professor of biochemistry in McGill University, Montreal, in recognition of his many contributions to endocrine therapy, and in particular of his work on the parathyroid gland

Chadwick Lectures

Four lectures on improved methods and materials employed in building, following on the two Bossom lectures delivered in December will be given at the Royal Institute of British Architects, 66, Portland place, London W, on Tuesdays, Feb 2nd and 16th and March 2nd and 16th, at 6 P M Further information may be had from that secretary of the trust, 204, Abbey House, London, S W 1

British College of Obstetricians and Gynæcologists

The quarterly meeting of the council of the College was held on Jan 23rd with Sir Ewen Maclean, the president, in the chair Gora Chand Nandi (Calcutta) and Mangaldas Mehta (Bombay) were admitted to the membership, to which the following were also elected —

Geoffrey Sheddan Adam Australia Richard Francis William Kinkead Allen India Doris Crystal Bates, Manchester Francis Arthur Bellingham Australia Edith Brown India Harold Henry Caple Canada William Clement Glasgow Duncan Iain Finlayson Birmingham William Frame Flint Glasgow Phillip Joseph Ganner Birmingham Arthur Lionel Gilbey Portsmouth Uma Pati Gupta, India William Hunter, Newcastle upon Tyne Claude Wilfred Alfred Kimbell New Zealand William Alexander Liston Edinburgh John Robertson McArthur Canada William Leonard MacCormac and Barbara Martin Macewen London Margaret Martin McDowell Halifax Kelvin Alexander McGarrity London and Australia Gerald Maizels London Gladys Helen Marchant India Charles Ferdinand Marks Sheffield William Ian Clinch Morris Edinburgh Harry Stafford Morton and Bryan Charles Murless London Dudley Clifford Racker Louis Rich and Charles Bernard Edward Rickards Manchester George Walter Robson Canada John Myrtle Sanson, Edinburgh Jacobus Wynand Schabort South Africa Lydia Torrance India William Waddell South Africa and Stanley William Wright Newcastle Staffs

The council elected committees in India for the provinces of Bengal, Assam and Orissa for the Bombay Presidency for the Madras Presidency Mysore Travancore and Hyderabad, for the United and Central Provinces and Bihar and for the Punjab North West Frontier Province and Sind The function of these committees will be to consider any matter bearing upon obstetrics and gynæcology in their respective area and to report to the council

Society of Apothecaries of London

At recent examinations the following candidates were successful —

Surgery—A Bagon, Univ of Manch E F Bullock, Univ of Leeds, F J H D De Marigny and P A Gardiner Guy's Hosp F W McKenna Univ of Sheff J Meynell Univ of Manch A P Mittra, Royal Colleges, Edin and F L Skinner, Univ of McGill

Medicine—J E R Palmer St Mary's Hosp, and W W Willson Univ of Oxford and St Mary's Hosp

Forensic Medicine—J E R Palmer St Mary's Hosp and W W Willson, Univ of Oxford and St Mary's Hosp

Midwifery—A A Beazeley Guy's Hosp, I W Claiman Univ of Manch R M Coplans and D S Edwards Middlesex Hosp J Meynell Univ of Manch C T Tahil Univ of Edin and W G Tillman, Guy's Hosp

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery F J H D De Marigny and A P Mittra

Hunterian Society

On Wednesday, Feb 17th at the May Fair Hotel, Berkeley-street, W, this society is holding a banquet to commemorate the 209th anniversary of the birth of John Hunter The hon secretary is Mr A E Porritt, 27, Harley street, London, W 1

Listerian Society

A meeting of this society will be held at King's College Hospital on Wednesday, Feb 10th, at 8 30 P.M., when Dr Alan Gregg, medical secretary of the Rockefeller Foundation, New York, will speak on psychological research All medical practitioners are invited to attend

Pharmaceutical Society of Great Britain

A lecture on the Addendum 1936 to the British Pharmacopœia 1932 will be given by Dr C H Hampshire, secretary to the Pharmacopœia Commission, at the house of this society, 17, Bloomsbury square, W C, on Feb 9th at 8 30 P M

Association of Clinical Pathologists

On Saturday, Jan 30th, the tenth annual meeting of this association will be held at the British Postgraduate Medical School, Ducane road, London, W The morning session will begin at 9 30 A M, and there will be a discussion on the diagnosis of gonorrhœa in which Dr G W Goodhart, Dr J O Oliver, and Dr Orpwood Price will take part At 11 30 A M short papers on the diagnosis of syphilis will be read by Dr J G Greenfield, Dr A G Signy, and Dr H C Lucey In the afternoon, from 2 to 4 P M, demonstrations will be given by Dr John Gray, Mr E J King Ph D, and Mr G A D Haslewood, Dr A. A Miles and Dr J Gray, and Dr Janet Vaughan On the Friday evening before the meeting a dinner will be held at 7 30 P M at the Holborn Restaurant, W C, after which the president-elect Dr S C Dyke will open a discussion on the present and future status of the clinical pathologist

Ella Sachs Plotz Foundation

The trustees of this foundation are anxious to make known the resources of their fund for the advancement of scientific investigation The foundation seldom or never offers stipends to investigators nor does it provide apparatus and materials which are ordinarily part of laboratory equipment Its special purpose is to give grants for the purchase of apparatus and supplies required for special investigations and for the payment of unusual expenses, including technical assistance The research should bear closely on medicine or surgery, and the maximum size of grants will usually be less than $500 In the thirteen years of its existence the foundation has made 282 grants and investigators have been aided in 29 countries Applications for assistance should arrive before May 1st including statements about the nature of the investigation the amount of money wanted and the way in which it will be spent The secretary of the executive is Dr Joseph C Aub Collis P Huntington Memorial Hospital 695, Huntington avenue, Boston, Massachusetts, U S.A

Sir Stanley Woodwark physician to the Westminster Hospital has been elected chairman of the justices of the peace for the county of London acting in the division of St Marylebone for 1937 He is a deputy lieutenant for the county

Royal Society of Arts

On Wednesday Feb 3rd at 8 15 P.M Lieut -Colonel Sir Arnold Wilson will speak to this society at its house in John street Adelphi W C on working-class insurance Tickets of admission may be had from the secretary

Society for Constructive Birth Control

On Wednesday Feb 3rd at 2 30 P M a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs Marie Stopes D.Sc. and Dr Evelyn Fisher Medical practitioners and senior students should apply for tickets to the hon secretary of the society 108 Whitfield-street London W 1

Grocers' Company Scholarships

To encourage original medical research the Grocers Company offers three scholarships each of £300 a year with allowances The next election will take place in May and further particulars will be found in our advertisement columns

British Association of Radiologists

On Friday Feb 19th at 5 30 P M at 1 Wimpole-street London W Dr E Lysholm of Stockholm will address a meeting of this society to which all medical practitioners are invited He will speak on radiological possibilities of demonstrating the exact location size and pathology of intracranial expansive processes

Superannuation for Nurses and Hospital Officers

It is nine years since King Edward s Hospital Fund for London initiated the federated superannuation scheme for nurses and hospital officers in which 1000 institutions all over the world now take part Nurses and hospital officers are now able before joining the service to assure themselves of a pension on retirement Full particulars can be obtained from the secretary of the Scheme 21 Cavendish-square London W 1

Royal Sanitary Institute

A discussion on the house as a home (design construction, and equipment as they affect comfort) will take place at a meeting at the Royal Sanitary Institute 90 Buckingham Palace road London S W on Thursday Feb 18th at 2 30 P.M The discussion will be opened by Dr H A. Fawcett principal assistant medical officer of the housing section of the public health department of the London County Council, Mr Percival T Harrison, borough engineer and surveyor for Finchley and Mr H H Clay divisional assistant to the division of public health of the London School of Hygiene and Tropical Medicine

Appointments

GOLDIE WILLIAM M B Aberd M R C P Edin has been appointed Research Worker in Arthritis at the Leeds Public Dispensary and Hospital

CUSACK, I B M B Durh , Whole-time Assistant to the Newcastle upon Tyne Radium Centre

HEGARTY MARGARET J M B Belf D P H Assistant Welfare Medical Officer for the County of Durham

LENNOX V N M D Lond Assistant Medical Officer for Rotherham

MARSHALL, C JENNINGS M D M S Lond F R C S Eng Visiting Surgeon to the Kingston and District Hospital

SPINK M S M D Camb Assistant Bacteriologist and Pathologist at the Jessop Hospital for Women Sheffield

London Homœopathic Hospital —The following appointments are announced —

SCHWARSCHILD, HERTA M R C S Eng Pathologist and Bacteriologist

TUCKER, W E B Ch Camb , F R C S Surgeon in Charge of the Orthopædic and Mechanotherapy Department and

ROWLAN, L G M B Glasg., D O M S Surgeon for Diseases of the Eye

Certifying Surgeons under the Factory and Workshop Acts : Dr J IRVING (Brigstock District Northampton) Dr A J BROWN (Ebbw Vale District, Monmouth) and Dr G D O CAMERON (Grassington District York) (W R)

Vacancies

For further information refer to the advertisement columns

Altrincham Cheshire St Anne's Home —Res. Surg O £200

Bath, Royal United Hosp —Two H.S s to Special Depts. Also H.P each at rate of £150

Bedfordshire County Council —Asst County M.O H &c £800

Birmingham Little Bromwich Hosp for Infectious Diseases —Jun. Res M O £300

Birmingham Maternity Hosp —Res Med O and Reg £900

Bradford Royal Infirmary —Res. Surg O £250

Bristol City and County —Asst. M O H £500

British College of Obstetricians and Gynæcologists 58 Queen Anne street W —Res Librarian £400

Bury County Borough —Deputy M O.H £750

Chelmsford and Essex Hosp —H.P and H.S. each £150

Chester County Mental Hosp —Deputy Med Supt. £675

Chesterfield and North Derbyshire Royal Hosp —H S at rate of £150

City of London Hosp. for Diseases of the Heart and Lungs Victoria Park, E. —H.P at rate of £100

Colonial Medical Service —Thirty Vacancies, £600–£ 00

Dewsbury and District General Infirmary —Second H.S., £150

East Ham Memorial Hosp Shrewsbury-road E. —H.P at rate of £150

Elizabeth Garrett Anderson Hosp Euston road N W —Asst Radiologist £100

Gloucester Barnwood House Registered Mental Hosp —Med Supt. £1500

Great Yarmouth General Hosp —H.S £140

Grimsby and District Hosp —Surgeon for Orthopædic Dept. and Fracture Clinic, £350

Grocers Company Grocers' Hall E C —Three Medical Res Scholarships, each £300

Guildford Royal Surrey County Hosp. —H.S., at rate of £150

Hereford, Herefordshire General Hosp —Hon Physician for Cardiological Dept

Hosp of St John and St Elizabeth, 60 Grove End-road N W —Clin Asst. in X Ray Dept £75.

Huddersfield Royal Infirmary —Cas O at rate of £200 Also H.P and Res Anæsthetist at rate of £150

Ilford King George Hosp —Hon. Physician

Lancaster Royal Albert Institution for the Feeble Minded. —Res Jun. Asst M O £375

L C C —Asst MO s Grade I and II £350 and £250 respectively

Leeds Public Dispensary and Hosp North-street —Anæsthetist 35 guineas

Liverpool and District Hosp for Diseases of the Heart —H P £100

Liverpool Royal Southern Hosp —Hon Asst Orthopædic Surgeon

Liverpool Sanatorium Delamere Forest, Frodsham —Sen and Jun Assts., £375 and £325 respectively

London Hosp E —Paterson Research Scholar and Chief Asst for Cardiac Dept , £400

Maidstone, Kent County Ophthalmic Hosp —H.S to Ear Nose and Throat Dept., at rate of £150

Maidstone West Kent General Hosp —H P., £175

Manchester Booth Hall Hosp for Children —Res Asst M O at rate of £200

Newcastle General Hosp —Venereal Diseases Clinic M O £500

Newcastle upon Tyne Barrasford Sanatorium. —Res Med Asst., £250

Newport County Borough —Asst M O.H , £500

Northampton Mental Hosp Berrywood —Third Asst M O £450

Norwich Norfolk and Norwich Hosp —H.S to Special Depts £150

Nottingham General Hosp. —H.S for Fracture and Orthopædic Depts., £300

Oxford University —Philip Walker Studentship in Pathology £300

Oxford Wingfield Morris Orthopædic Hosp Headington —Res H.S £100

Pendlebury Royal Manchester Children s Hosp —Asst. M O for Out patients Dept., at rate of £150

Plymouth Prince of Wales's Hosp Devonport —H.S at rate of £150 Also Jun H.S and Res Anæsthetist and H S to Special Depts., each at rate of £1 0

Portsmouth City —Asst Dental Surgeon £450

Princess Elizabeth of York Hosp for Children Shadwell E —Asst. Surg

Queen Charlotte s Maternity Hosp Marylebone road N W —Res M O for Isolation Hosp at rate of £200

Queen s Hosp for Children Hackney road E. —Cas O At rate of £100

Queen Mary's Hosp for the East End E —Hon Asst Physician to Psychological Medicine Dept.

Reading Royal Berkshire Hosp —Res Anæsthetist £2[illegible]

Royal Air Force Medical Service —Commission

Royal Cancer Hosp Fulham road S W —H S to Radium Dept at rate of £100

Royal Free Hosp Gray s Inn-road W C —Hon Asst Physician

Royal Northern Hosp, Holloway N —H P also Obstet H S each at rate of £[illegible]0

SUNDAY FILMS AND BIRMINGHAM HOSPITALS—The sum of £9000 has been allocated for distribution among the Birmingham hospitals under the Sunday Entertainments Act

NOTES, COMMENTS, AND ABSTRACTS

NEW GROWTHS IN ANIMALS

THE tumours of domestic animals are of little economic importance, and have therefore been little studied. A possible explanation of their apparent rarity is that few domestic animals survive to old age. This explanation is supported by the fact that in dogs, which often die a natural death, new growths are not uncommon. On the other hand, if they often caused death in cats or horses the fact would be recognised.

Apart from the transmissible tumours of birds which have been carefully studied, not much is known about animal neoplasms and text-books on the subject are scarce and incomplete consisting almost entirely of rather elementary morphological descriptions, many of them based on too few cases. In an attempt to fill some of the gaps C Jackson in South Africa has classified and described *all* the new growths in the Onderstepoort collection of pathological specimens, and records his findings in the *Onderstepoort Journal* (1936 6 1) The collection of some 18 000 specimens contains only 600 neoplasms, and this illustrates their relative unimportance in veterinary pathology It is necessary to mention however what type of material is likely to find its way to the laboratory Onderstepoort as the centre of veterinary research in South Africa is fed by Government veterinary officers in the field and by municipal officers such as abattoir inspectors but the bulk of material is collected during post-mortem examinations carried out at the laboratory All species of farm animals are examined but because many aged horses are used for virus and antiserum production more examinations are made of aged horses than of aged animals of other species. In all 119 tumours were examined from horses, 108 from cattle 80 from sheep 40 from goats 4 from pigs, 72 from dogs, 2 from cats, and 203 from poultry The attention nowadays paid to lympho-granulomatous conditions of birds (e g fowl paralysis, Marek s disease, Newcastle disease) makes it probable that a more careful search is made for tumours in birds than in mammals. Comparatively few dogs and cats are sent to the laboratory in the course of ordinary routine and Jackson must have largely depended on the coöperation of a very small group of private practitioners in obtaining material from domestic pets.

Thus the species incidence of animals tumours as recorded by Jackson cannot be considered as a true random selection amongst species. This is particularly evident when one considers the relatively small number of tumours from dogs—a result partly of the lack of post-mortem material and partly of the shortness of the life of dogs in South Africa compared with England For various reasons including disease and neglect many dogs never pass maturity in South Africa and comparatively few receive skilled veterinary attention. In England, on the other hand the majority survive distemper and the perils of the road to reach a ripe old age. Even the poorest owners manage to find the modest shilling which ensures attention for their pets when sick and the presence of neoplasms is thus brought to the *attention* of pathologists and a vast amount of material is available for investigation Hitherto little has been done to make adequate use of such material but Jackson s example may stimulate others to cover the ground he has been forced to neglect

In reporting his results Jackson gives little notice to tumours that are easily diagnosed and describes in detail those he found hard to classify Besides recording simple morphological features, he has made nuclear : Nucleolar (n : N) ratio estimations and estimations of mitotic indices has examined the significance of other nuclear inclusions and has investigated the intracellular matrix of different kinds of tumours.

A quick and reasonably accurate method was evolved for estimating the n N ratio by means of a dot-and circle graticule" inserted into the ocular of the microscope As regards the interpretation of the n N ratio Jackson emphasises that attention must be paid to the n N ratio of normal cells of the particular tissue under consideration before any significance can be attached to this ratio in tumour cells. In using the n N ratio as an index of malignancy this term must be understood to embrace not only metastasis but also very rapid invasive growth. The difficulties underlying the interpretation of the mitotic index include a lack of knowledge of the rate of division of nuclei of different types of normal cells in various animal species and of the part played by amitotic division in the growth of animal tumours Furthermore the difference between the mitotic indices of benign and malignant tumours is merely one of degree there being no clear-cut line of demarcation Nevertheless the mitotic index does serve to express with some precision statements such as " mitotic figures are frequent "

Average mitotic indices have been worked out for some of the commoner tumours but the case-groups were usually too small. In 11 canine contagious venereal tumours the average was 6·6 In 30 acanthomata from various species it was 5 0 It is noteworthy that in 6 canine basal-celled epitheliomata it was only 1 8 Apart from the contagious venereal tumours and acanthomata, which had maximum indices of 15 and 13 respectively the maximum indices encountered in other tumours were surprisingly low In estimating the mitotic index of a tumour a count was prepared in a part of the field showing most mitosis the object being to learn the worst of any growth

Jackson groups his tumours according to the tissue of origin—epithelium mesothelium, and endothelium —and provides many excellent photographs and photomicrographs. Where suitable material was available the histogenesis has been studied and the resulting discussions are unique and valuable The tumours recorded for the first time include carcinoma of the small intestine and carcinoma of the pancreas of the sheep thymoma in the goat embryonal nephroma in the horse, gliomas in the brain of the fowl cutaneous neurofibromatosis in the fowl probable *sympathogonioma of the base of the dog's* heart (reticulo-) endothelioma of the liver and spleen of the sheep pericardial mesothelioma in the horse and myolipoma of the vagina of the bitch A special study has been made of certain epitheliomata of fowls and sheep characterised by excessive keratinisation of the cornu cutaneum. Also an attempt has been made to classify certain cutaneous and apparently contagious neoplasms commonly found in equines in South Africa, which seem to stand half way between the granulomata and sarcomata. As many as 37 per cent. of the tumours of equines fall into this category, for which the name sarcoid ' is suggested

The tumours commonly found in the various animal species are placed in the following order of numerical importance :—

Equines—Sarcoids acanthoma melanotic sarcoma, gland-celled carcinoma

Cattle.—Acanthoma gland-celled carcinoma papilloma, false neuroma

Sheep—Gland-celled carcinoma, acanthoma

Goat—Acanthoma melanotic epithelioma.

Dog—Contagious (venereal) tumours acanthoma, basocellular epithelioma.

Poultry—Lymphocytoma gland celled carcinoma leiomyoma mixed-cell sarcoma.

Other types of tumour constituted less than about 5 per cent of the total tumours in each animal species

COLDS AND INFLUENZA

Most of us would like to know "How to Escape Colds and Influenza," but the booklet with this title, written for the laity by "a well-known bacteriologist" and "a London physician," and published by Leonard Hill, Ltd , 17, Stratford-place, London, W 1, at 6*d* , cannot be said to contribute anything very new towards solving the problem The usual counsels about diet, clothing, cleanliness, and the avoidance of chill and fatigue are set forth, and paper handkerchiefs are recommended for those who have taken the infection Unlike many, the authors put considerable faith in the usefulness of oral vaccines, but when emphasising the evils of under-ventilation and overfeeding they are on surer ground Several appendices, interspersed with advertisements, are included There is a note on the ionisation treatment of hay-fever as practised at St George's Hospital and the authors have coined in "a bombardment of germs" a new noun of assemblage Some may think that here as elsewhere too much stress is laid upon the ubiquity of germs and not enough upon resistance to infection More regard to the cultivation of physical hardihood, which is possible even in crowded cities, may be of greater prophylactic value than much gargling and spraying

A note prefacing this little book says that "the etiquette of the medical profession does not permit the authors to append their names to a medical book written for laymen, but the publishers vouch for their high professional authority"

FATTY INFILTRATION

Lately it has been shown that fatty changes in the liver and the heart are largely, perhaps entirely, the result of the infiltration of fat In view of these findings Dr John Duncan Hay has performed a series of experiments upon rabbits, investigating the effect of starvation on their kidneys, and he reported his results on Jan 14th to the Liverpool Medical Institution. The rabbits had been starved for seven days and then killed The amount of fat in the kidneys and its iodine value was estimated, a control series of unstarved rabbits being similarly investigated The histological examination in the starved series demonstrated large amounts of isotropic fat in the kidneys, mainly in Henle's tubules Chemically also the percentage of fat was shown to have been raised, and the close relationship between this and the amount seen in the sections proved that the fatty changes were largely due to infiltration The degree of adiposity of the animals was estimated by weighing the intra abdominal fat deposits, and was found also to be closely related to the amount of fat in the kidneys, estimated chemically and visually This showed that the fatty changes in the starvation kidney depended on the amount of fat available in the rest of the body for mobilisation and transport The results of the iodine value estimations were inconclusive, neither supporting nor seriously invalidating the conclusions drawn from the other findings

In a discussion that followed Dr Hay's paper Dr R T Chadwick commented on the observation that fatty infiltration took place in starved rabbits only when the animal had been originally well supplied with fat stores He had noticed in the liver and kidneys of children dying of unrelieved pyloric stenosis that there was no trace of fatty infiltration, whereas fatty infiltration was conspicuous in the same organs of children dying of unrelieved intestinal obstruction, who were usually very well nourished Dr T F Hewer also said that Dr Hay's views were in accord with what he himself had seen at autopsy in many cases He instanced the examination of two persons dying from uncontrolled hæmorrhage, one an obese woman who had antepartum hæmorrhage for four days and the other an emaciated man with a gastric ulcer The organs in the woman, who had abundant fat depôts, were heavily infiltrated with fat, while those of the man showed only a trace There seems thus to be little doubt that in the kidney at least a high proportion of the visible fat in "fatty change" is derived by mobilisation from the fat depôts of the body

Curious Advertising —A practitioner in South London writes "Surely modern ways of advertising are curious The following telegram reached me before 8 o'clock one morning and appeared before opening to be an urgent message Strongly recommend —— for personal protection and that of patients in present flu epidemic (Signed)—— This will not redound to the popularity of the firm in question "

Annual Charities Register, 1937 —We have received from Messrs Longmans, Green and Co Ltd , a copy of the forty-fourth edition of the register and digest of charities in or available for the metropolis (pp 530, 8*s* 6*d*) In the prefatory note is a remark that much care has been expended on the index, and this is evident, for there are more than 3000 items on the 56 pages of the index, making it possible to turn up any desired information at a moment's notice By dint of careful editing, revision, and concentration this book has become in the course of years a model of its kind , it is well nigh indispensable for those engaged on public work of any sort within the metropolis

"Buried Treasure"—In a leading article with this title last week a line dropped out of the penultimate sentence which should have read In any case it is surely undesirable, if material is worth publishing at all, that the only medium chosen should be an un-indexed official report of which no account is taken in the Cumulative Index, the Zentralblatt or any of the other means of reference that psychiatrists use

ADDRESSES AND ORIGINAL ARTICLES

PROGRESS IN THE TREATMENT OF FRACTURES *

BY R. SALISBURY WOODS M.D Camb F R C S Eng
FORMERLY MEDICAL OFFICER IN CHARGE OF THE FRACTURE CENTRE, 4TH LONDON GENERAL HOSPITAL

IN the last 25 years enormous improvements in treatment, comfort and results have been brought about by the mass experience of the late war But since then the advance has happily continued sick wastage from the majority of fractures has now been reduced to a minimum, and permanent disability should be rare or negligible if modern treatment is carried out.

The Pre War Position

For many years before the war it had been the custom to reduce fractures by manual traction under general anæsthesia. The injured limb was then swathed in cotton wool and put up in a plaster-of Paris casing But, as the initial swelling subsided the loose layer of wool allowed of considerable movement at the site of fracture Moreover no attention was paid to the function of the limb which merely lay in bed and suffered atrophy from disuse. Even if and when crutches were employed no normal weight-bearing was allowed or indeed possible until sound union had occurred.

RESTORATION OF FUNCTION

For some years before the war however the doctrine of early massage and physiotherapy had become fashionable and plaster of Paris fell into desuetude. Padded wooden splints like the back splint with foot piece and side-pieces for the leg the long Liston for the thigh and the internal angular for the forearm became standardised. These offered the attraction of easy partial removal in order that the limb could be given massage and electricity the aim of which was to counteract the stiffness of neighbouring joints and weakness from disuse which were found naturally to follow a fracture But restoration of function to the injured person was very painful and slow In major lower limb fractures weight bearing was not attempted (however gingerly) until after 8–10 weeks the atrophied muscles required at least a further 2 months to regain their full power and joints were often impaired for life Loss of employment and sick wastage lasted not uncommonly for at least 6–12 months and as surgical specialist to insurance companies I still see such results In fractures of the femur however an advance had been made in that the principles of suspension and axial traction were brought into play by the Hodgen frame splint in conjunction with the weight and pulley

FIXATION OF FRAGMENTS

Just before the war open operation and fixation of the fragments by plates and screws wires or intramedullary pegs had come into vogue through the work of Sir Arbuthnot Lane Dr Lambotte and others and in 1915 Hey Groves's book on Modern methods in treatment of fractures was still mainly concerned with operative treatment although he decried it for open fractures During the war every gunshot fracture— G S W with fracture — was necessarily open and infected. Consequently the wound was dealt with by excision of skin edges and toilet of the track, but no internal splinting was attempted. This was on the principle that no open fracture should be plated, owing to the aggravation and prolongation of sepsis by the introduction of foreign bodies

CONTINUOUS TRACTION

As operative fixation was therefore contra indicated in treating the wounded the principle of continuous traction probably adapted from Hodgen's splint regained its pride of place and developed out of all recognition Traction reached its height of fame and efficiency when used for fractures of the femur in conjunction with the Thomas's splint suspended and counter poised from a Balkan beam. The actual pull was applied either by adhesive media or by direct skeletal traction

Adhesive media.—Strips of adhesive plaster on each side of the limb leading off to a stirrup and weight over a pulley These were apt to snap suddenly after several weeks causing great pain and alarm and needed renewal. They also irritated the skin and could not of course be applied at all where the surface was badly involved below the knee Nevertheless the method was generally satisfactory for fractured femurs and it was the most widely used

Sinclair's foot piece consisted of a wooden sole fixed firmly to the dorsum of the foot by overlapping strips of glued tape From its margins small rings enabled the coupling of a tractile force Many swore by this but I confess I swore *at* it because—perhaps from lack of previous continuity of treatment and ideas—a number of cases arrived at the centre where I was employed with sloughing of the skin and even of the tendons of the dorsum of the foot At any rate it was not fool proof

Direct skeletal traction took the form of (1) the ice tong calliper gripping into femoral condyles (2) Steinmann's pin, transfixing the tubercle of the tibia; and (3) Finochietto's stirrup passing anteriorly to the tendo Achillis and pulling on the superior surface of the os calcis It enabled far greater force to be applied in refractory cases than could be withstood by adhesive devices Personal experience of all varieties showed that each had its virtues For instance Finochietto's stirrup was reserved for cases where the skin above was so severely damaged that an extension could not otherwise be applied The danger of sepsis supervening was exaggerated even in cases of gunshot wounds, and we certainly did not meet it This factor of *suspension* added enormously to the comfort of the patient, especially in the dressing of posterior wounds and the use of the bed pan.

Continuous traction gave splendid results and in the fracture wards of the 4th London General Hospital (Woods 1923) despite sepsis and severe comminution the average shortening was less than 1 cm which does not interfere with function thanks to compensatory tilting of the pelvis Ambulatory treatment in a walking calliper followed in 4–8 weeks with all the benefits of physiological activity The principle was also used *in fractures of the upper* limb It was simple safe and convenient on active service for the Thomas's splints were interchangeable for right or left limbs, and the same pattern could be used in the trenches at the base or in England. Continuous traction—from a Kirschner wire through the tubercle of the tibia—is even now the best modern treatment for fractures of the femur

Post-war Progress

DIRECT OPERATION AND INTERNAL SPLINTING

Nevertheless surgery has its fashions and on returning to civil life with complete asepsis and

---

A lecture to the Cambridge University Medical Society "every modern convenience" there was a tendency to maintain the reduction of difficult fractures by the attractive gadgets that were at hand for the purpose of internal splinting Most of us resorted to them, and on the whole the patients did well. Anything definitely fixative seemed preferable to months of continuous traction Only really awkward fractures were operated upon, when the splints in use failed to meet the case, and compound ones never

A few examples may illustrate operative treatment

CASE 1 —A very muscular undergraduate on Nov 7th, 1924, sustained a comminuted fracture of his right femur *in its middle third while playing rugger* It was put up on a Liston splint, and he was transferred at about 6 P M to a nursing home and *referred to me* A Thomas splint, with 12 lb strapping extension, was applied and suspended from a Balkan beam Nov 9th X ray report unsatisfactory Nov 11th open operation A 10 in incision on lateral aspect of right thigh, fragments levered into accurate alignment by lion forceps, main shaft repaired by Lane's plate and 6 screws The third fragment (on the postero medial aspect) was then wired to the reconstructed shaft (Fig 1) Nov 17th flexing iron added to Thomas's splint, knee movements good Nov 20th *extension removed* Dec 20th up on crutches and a walking calliper, after 6½ weeks June 8th, 1925 knee movements full, walks without a limp, has played tennis

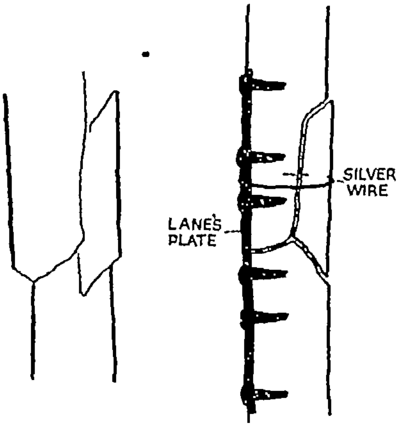

FIG 1 (Case 1) —Comminuted fracture of right femur (anteroposterior view) fixation with Lane's plate the third fragment being wired to reconstructed shaft.

It is relevant here to recall that in 1922 Hey Groves had written "I believe that operation ought to be the routine treatment for the majority of complete fractures of the shaft of the femur in adults of active life"

CASE 2 —A schoolmistress, aged 32, on Dec 18th, 1926, received a fracture of the upper end of tibia, into the knee joint, in falling from bicycle Put up on a Thomas's splint where she lay, 12 lb extension applied on admission to a nursing home Dec. 23rd radiograms showed a fracture of the right tibia into the middle of the knee joint, *with outward dislocation of outer fragment* of tibia on femur, the joint completely unstable, and torsion of articular surface of tibia Dec 24th fracture exposed by operation, and outer edge of tibial fragment united by two short oblique plates to the main shaft, after much difficulty in manœuvring, knee joint full of blood, which was evacuated, and the capsule was sewn up, fascia and fat brought over screws She was put back on Thomas's splint Gentle movements to the knee joint after a week She went back to teaching in 2 months In 1936 she could practically sit on her heels while kneeling and there was no disability She does climbing and plays tennis and other games

CASE 3 —On Feb 25th, 1928, an undergraduate playing rugger *suffered* a severe backward dislocation of his ankle joint, with vertical fracture of shaft of tibia into joint, and of lower third of fibula which occurred when he was tackled, while turning to kick. The dislocation was easily reduced, but the problem was how to promote *early movement* when upper mortice for the astragalus was entirely unstable In the contemporary view, such movements would shed osteoblasts into the disrupted joint, on the other hand, the avoidance of this by prolonged immobilisation would also have produced a stiff ankle *from adhesions It therefore* seemed proper to secure the mortice by open operation, and then to begin early movements

Feb 29th operation with axial incisions on medial and lateral aspects of lower third of leg, both fractures were exposed In that of the tibia, the periosteum was sewn tightly over, to clamp the fracture, after more accurate reposition In the fibula the position was improved by moving some intervening muscle, and the fragments were secured by stout silver wire, suspension in Neville's swing cradle Ankle movements from very beginning Regained almost complete range in 10 days

April 17th Mr C H Frankau saw him in London and wrote "The movements are practically perfect" April 19th started walking with shoe raised on the inner side Eventually no thickening, no disability, and *played rugger again* When seen in 1935 after 7½ years, it was impossible to distinguish his injured ankle from its fellow

It may be recalled that in 1908 Clinton Dent, writing on the after effects of [illegible] injuries among the police, stated that he "had difficulty in remembering a case of Pott's or Dupuytren's fracture which had *sufficiently recovered to resume* police work."

BÖHLER'S METHODS—MAINLY NON OPERATIVE

In the last few years the teaching of Lorenz Bohler of Vienna has revolutionised the whole treatment of fractures The cardinal features are —

1 Local or regional anæsthesia

2 Immediate and accurate reposition of the displaced bone ends

3 Absolute fixation of the reduced *fragments* until union has occurred, by [illegible] plaster-of Paris splint, helped in some cases by [illegible] wires inserted through the shaft at each end, and embedded in the plaster

4 Immediate *functional restoration of movements,* including (in the lower limb) weight-bearing where possible, while the necessary fixation is maintained.

5 No open operations, even in compound or "closed" fractures except where there is separation of the fragments—e.g., of the olecranon or patella—or in some fractures involving joints, in which the joint surface is twisted—e.g., upper and lower ends of humerus or in upper end of radius, in subcapital intra articular fractures, of the neck of femur and I might add, in Case 2, of the upper end of the tibia the articular surface

Bõhler includes among "errors in the treatment of recent open fractures" —

10 Setting the fracture in the open wound by means of levers and instruments This is liable to force infective material into the spongy bone and marrow cavity

11 Bone suture by the use of large foreign bodies, particularly plates and screws Infection and osteomyelitis are the common results of this

And further he states —

"Operative treatment involves great dangers, because in every fracture the soft parts are also severely injured and because many vessels have been torn by the causative violence At the operation, the bone fragments must be widely exposed, and further vessels torn Most dangerous of all is the operative fixation of fragments in open fractures—and this according to many surgeons is the very object of the operation"

In normal tissues, bone operations conducted with suitable technique are well nigh without danger Of ununited fractures, Böhler says —

"Faulty position of the fragments and interposition of soft parts may be the cause Most frequently it lies in unsuitable treatment" Primary operative treatment by means of buried foreign bodies, particularly Lane's plates, is the frequent cause of pseudarthrosis Henderson of the Mayo Clinic found that in 211 cases operated on for pseudarthrosis 66 per cent were due to fixation with Lane's plates, and Scudder found that 70 per cent of 32 cases resulted from the same cause

Gray of San Francisco has examined 34 725 cases and has found that the period of recovery of fractured femurs treated by operation was twice as long as that of those treated conservatively; that the expense of treatment was three times as great and the amount of compensation doubled In the lower leg of those subjected to operation, expense and compensation were about 50 per cent. higher than in the others.

ORDINARY SPLINTS NOW OBSOLETE

These really basic requirements, as preached by Böhler of accurate reduction fixation and function are not satisfied by most of the splints whose employment was a standard routine in hospitals until the last few years, and which are still in current use in a great many places. To take as a common example the back splint with foot piece for fractures of the tibia and fibula, with or without Cline's side splints, and whether suspended from a Neville's cradle or not, this contraption never properly immobilised the fragments of a *fractured tibia* and fibula, and was useless for transport in comfort. The reduction was usually far from accurate, or at any rate was not secure the resulting distortion of vessels produced much oedema and the vertical foot piece denied the natural position to the foot To remedy this the limb was subjected to daily massage with or without electricity which necessitated interference with the splint and with the fractured leg and could hardly have contributed to the absolute fixation that is now held to be essential in treatment No function was attempted for weeks and no weight bearing until sound union had taken place in about 2 months.

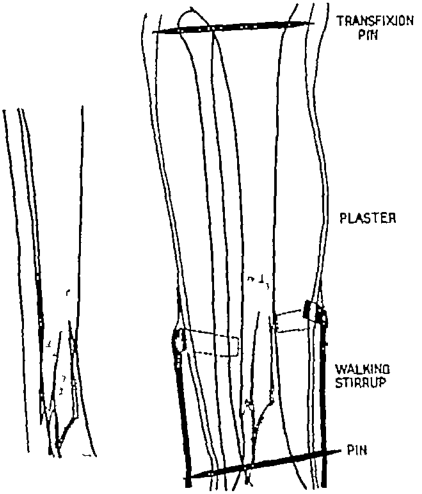

FIG 2 (Case 4)—Multiple fractures of right tibia (antero-posterior view) Left: after manual traction only; right: after 5 weeks weight bearing beginning within one day of operation Fixation with transfixion pins and plaster cast position being maintained by 45 lb. of traction with Kirschner wire through os calcis until the cast had set.

In modern treatment fractures of the tibia and fibula are accurately reduced under local anaesthesia by screw traction if necessary and the position absolutely maintained by a non padded plaster of Paris splint of Cellona bandages which sets immediately In simple and particularly transverse fractures walking may be begun almost at once In oblique and multiple fractures where telescoping is to be feared, ambulatory treatment is nevertheless possible by transfixion fixation of the fractured tibia by means of stout transverse steel pins above and below the fractures whose projecting ends are embedded in the irregular cylinder of plaster The saving in sick wastage and hospitalisation is nothing short of dramatic, and *function* replaces the usual dreary and expensive ritual of months of physiotherapy

CASE 4.—An undergraduate who was playing hockey on Oct 23rd, 1936 was tripped by a stick and fell sustaining severe injury to his left leg Tremendous swelling over the lower half of the tibia; ankle inverted obvious crepitation By manual traction, under local anaesthesia, the fractures were reduced and the limb put up in a cellona cast from sole to mid thigh. Oct 24th: radiography showed multiple fractures (Fig 2) and although the position had obviously been greatly improved there was some angulation of the tibia laterally; and even the fibula itself though intact was bent outwards It was therefore decided that this must be further improved and sick wastage minimised by operation.

Oct 25th: the plaster cast was removed under anaesthesia, the leg cleaned up, and sterilised. A Kirschner wire was drilled through the os calcis and screwed taut in a Max Page stirrup. This was then connected to a screw traction apparatus, with spring balance the knee being flexed over a bar in a Böhler extension frame The fragments were subjected to a 45 lb pull, and manipulated into alignment The angulation being corrected, tension was maintained while stout transfixion pins were bored through the tibia above the ankle joint and through the tuberosity and left with their ends projecting The limb was then put up in a mid thigh cellona cast by the usual technique thereby embedding the pins and the Kirschner wire in a rigid irregular cylinder The wire was then withdrawn (releasing traction) and the punctures sealed. The alignment appearing to be perfect a walking stirrup was applied and the projecting spikes padded with plaster knobs. Patient was radiographed again and alignment now seen to be perfect.

Oct 26th: he was very well toes warm; no oedema. He was encouraged to walk with sticks about 10 yards and back again without discomfort *20 hours after operation*

Oct 31st: he walked about when he felt like it and had already walked up and down the stairs without help. He was discharged to go back to college 6 days after operation.

Nov 12th: he had dined in hall, attended lectures and walked about the town He had no pain and had never used a crutch Radiograms show *perfect* [illegible] of tibia (Fig 2) with slight curvature of fibula

By analogy with a similar case published [illegible] there was every reason to hope that, when the [illegible] was removed about 10 weeks after operation, the [illegible] would regain full movements of the knee and ankle [illegible] immediately Further the usual weeks or [illegible] of massage and electricity [illegible] if not entirely eliminated by the [illegible] of the limb from the [illegible] as regards the troublesome oedema [illegible] fractures by the temporary [illegible] Elastoplast puttee to the [illegible] the cellona cast is removed

Jan 21st 1937 [illegible] the knee [illegible] applied after 8 weeks [illegible] further 3 weeks the patient being [illegible] The fracture soundly unit[illegible] and there disabilit[illegible]

Transfixion fixation may also be used by means of Kirschner wires, drilled through the radius and olecranon, for those fractures of the forearm in which perfect reduction cannot otherwise be attained or maintained.

Other examples of obsolete splinting are the common splints used for a Colles's fracture, such as Carr's, "cock up," &c These, too, were usually employed after imperfect reduction, and anæsthesia, if any, was general rather than local They were rarely comfortable, lacked complete control, and moreover were also removed for daily massage, and later for movements as well, in the belief that a stiff wrist joint would follow immobilisation The hand was not used for up to 3 weeks Nowadays, immediate reduction is followed by complete fixation in a non padded cellona splint, with the wrist joint half way between flexion and extension, and between pronation and supination, for 3–4 weeks The fingers are moved immediately the plaster has set, followed by pronation and supination of the forearm The shoulder and elbow joints are moved with the hand behind the back, and over the head. Exercises with a puller machine may begin on the third or fourth day It is only necessary to carry the arm in a sling for a few days, and after 2–3 days the hand can be used for light duties, such as writing and sewing, and for woodcutting in 7 days It is particularly pleasing to women to be able at once to arrange their hair and to tie their aprons The more the patient works, the better his progress When the cast is removed the movements at the wrist are full, free, and painless, and the ultimate disability nil.

SOME DIFFICULT FRACTURES

Fractures of the navicular (scaphoid) were formerly regarded as very intractable, liable to non union, and operation for removal often followed. Modern treatment in recent cases is similar to that of a Colles's fracture, except that the wrist is put up slightly extended, and in ulnar abduction, and that it is left absolutely immobilised for at least 6 weeks Radiography is then repeated, and obstinate cases *may* take as long as 4 months Böhler himself was successful in obtaining bony union and complete mobility of the wrist in 158 cases, without a single exception The delicate blood supply of the scaphoid has to be re established from the peripheral into the central fragment, and if any movement of the wrist is permitted, the fragments glide over one another and the growing vessels are severed. Consequently the orthodox treatment of massage and passive movement should never be employed. Indeed, it was wholly responsible for the previously bad results

Fractures of the shaft of the femur—The principle of continuous traction, elaborated from the experience of the late war, still holds the field here, save that direct skeletal traction has developed, and practically replaced the alternative methods depending on adhesive plaster, or glue—e g, Sinclair's foot piece

A transfixion pin is introduced through the tubercle of the tibia under local anæsthesia It is more rapid, involves less movement of the fractured limb (shock and damage), and enables much greater tractile force to be exerted The pin is removed in 3 weeks, lest the knee joint should become lax, and an adhesive extension is then adopted, but the plaster should include the whole thigh, so that it grips the whole of the muscle cylinder that causes shortening Another is similarly applied to the leg Each extension is attached to separate weights over pulleys and we have a picture of war time axis traction Weight bearing is usually safe in about 8 weeks, but is not allowed until the patient can lift the limb easily and without pain, and until the site of the fracture is no longer tender on pressure A firm supporting puttee of elastoplast is then applied for 3 weeks, from the webbing of the toes to the thigh above the fracture This is a great advance in the prevention of the troublesome œdema that followed in fractures of the lower limb

Fractures of the neck of the femur—It is perhaps here that modern treatment shows the most dramatic progress Formerly it was the rule to apply weight and pulley extension, the limb being widely abducted. Where the general condition allowed of sufficient time, bony union took place with some shortening, but the patient was crippled mainly by the ankylosis of the hip joint, following imperfect reduction and prolonged immobilisation, but many died of hypostatic pneumonia In 1915 Cathcart wrote "If there is no union at the end of 12 weeks, the patient must depend on bearing his weight upon ligaments" Statistics of 1922 show that barely 25 per cent. ever recovered good function In young and active patients, surgeons were groping for operative measures which would prevent the disabling sequel of coxa vara and allow earlier movements, but they were content to drive into the neck of the femur from the trochanter nails or pegs that eventually became loose. In 1916 Hey Groves foreshadowed modern technique when in criticism of this he said "What is required is a *massive* peg, capable of filling up the neck of the femur, supporting it at the correct angle with the shaft, and stimulating the formation of new bone for the natural process of repair" This requirement is now fulfilled by Smith Petersen's pin, which originally was introduced into the neck of the femur by free exposure of the hip joint, involving a big operation More recently, however, Sven Johannson in Göteborg and M. Jerusalem in Vienna have independently worked out an extra articular method. The pin is triradiate in cross section, and is perforated so that it is thereby guided into position along a previously introduced wire, and driven home with a special hollow punch This may, however, cause separation of the fragments, so they are reimpacted lightly by a few final taps from an "impaction punch" The various stages are verified by X ray examinations The results are excellent, even in the aged, and the dangers minimised by using this method.

After 3 or 4 weeks the hip, knee, and ankle can be moved through a full range, and in 6 weeks the patient should be able to walk really well.

Conclusion

The treatment of fractures is an extremely large subject, and it has only been possible roughly to sketch the outlines of improvements evolved in the last 25 years At present the best results appear to be generally obtainable from non operative methods of safety and improved technique, which in many instances allow of natural function immediately By these measures, our generation will benefit in a manner unknown to our predecessors, in reduction of the pain, sick wastage, and lasting disability, that were previously endured by fractured humanity

A NEW FACTOR IN THE PRODUCTION AND CURE OF CERTAIN MACROCYTIC ANÆMIAS

By Lucy Wills M.A Camb M B Lond

P W Clutterbuck O B E D Sc. Ph.D Leeds, F I C

and

Barbara D F Evans M R C S Eng

(From the Departments of Bacteriology and Biochemistry London School of Hygiene and Tropical Medicine and the Pathological Unit Royal Free Hospital)

It is well known that Marmite and similar autolysed yeast preparations are active curatively in tropical and other macrocytic anæmias in which there is little or no evidence of alteration in gastric secretion (Wills 1934 Vaughan and Hunter 1932) Further such yeast extracts are active hæmopoietically in true pernicious anæmia after incubation with normal gastric juice (Strauss and Castle 1932 Groen 1935) Castle's theory postulates the formation of a liver hæmopoietic principle from the interaction of an extrinsic factor present in certain foodstuffs with an intrinsic factor present in normal human gastric juice This liver principle has recently been isolated in a relatively pure form known as anahæmin by Dakin and West (1935 1936) These workers point out that anahæmin because of its method of preparation can have no chemical similarity to the liver factor earlier isolated by Cohn McMeekin and Minot (1930) which these authors had shown also to be active curatively in pernicious anæmia The nature of the yeast factor or factors is unknown

In view of the fact that autolysed yeast is a potent source of Castle's extrinsic factor it has been suggested that the principle in yeast active in the treatment of tropical macrocytic anæmia is identical with the extrinsic factor of pernicious anæmia and that tropical macrocytic anæmia is therefore a deficiency state due to a lack of this extrinsic factor in the diet (Wills 1934) The similarity of the blood picture in pernicious anæmia and in the tropical condition and the fact that liver preparations are curative in both lend support to this view There are however certain difficulties in accepting this theory If tropical macrocytic anæmia is due to a lack of extrinsic factor in the diet then the final deficiency in the body must be in the liver principle In classical pernicious anæmia a deficiency in liver principle is associated not only with a macrocytic anæmia but also with an increased bilirubin content of the blood and an increased output of urobilin in the urine In uncomplicated tropical macrocytic anæmia although the anæmia is macrocytic there is no increase of blood bilirubin or urinary urobilin (Wills and Mehta 1930) There is also no increase in blood bilirubin in the rhesus monkey suffering from nutritional anæmia. Further it is a remarkable fact that no description of nervous lesions in the tropical condition has yet appeared

With a view to investigating the problem of the nature of this nutritional macrocytic anæmia and of the hæmopoietic factor present in yeast the animal experiments described below were undertaken.

In a previous paper (Wills and Stewart 1935) the production of a macrocytic anæmia in the rhesus monkey has been described and the reason given for considering the anæmia as the animal counterpart of tropical macrocytic anæmia. The same methods were used in the present work. The activity of any extract was judged by the height of the reticulocyte response and the rise in the red cell count and the hæmoglobin percentage in a properly controlled animal. In view of the work of Miller and Rhoads (1933 1935) on the failure of dogs in which a macrocytic anæmia had been induced by dietetic means to respond to parenterally administered liver extracts (the dogs were infected with Bartonella) the effect of intramuscular administration of the liver extract Campolon on our anæmic monkeys was first investigated Campolon was used as it is known to be active curatively when given parenterally in the tropical macrocytic anæmia of man Animals so treated responded well though surprisingly large doses were often necessary to induce maximal responses

Whilst this work was in progress, the liver factor curative in true pernicious anæmia became available in the highly purified form known as anahæmin. It was therefore desirable to determine whether anahæmin was also active curatively in the nutritional macrocytic anæmias of the rhesus monkey It was found that a sample which was reported by Ungley (private communication) as active in two cases of pernicious anæmia was absolutely inactive, even in large doses in the macrocytic anæmia of our experimental animals. Five monkeys were treated: two received 100 mg daily for 10 days during which time there was no reticulocyte response and the red cell counts of one animal fell and of the other remained stationary after a further 6 days in which their condition remained unchanged both animals made excellent responses to campolon. The activity of the relatively crude liver extract campolon and the complete inactivity of the purified factor anahæmin both given parenterally suggest that the causation of nutritional macrocytic anæmia of monkeys cannot be explained satisfactorily by assuming a simple lack of Castle's extrinsic factor in the diet and therefore of the liver principle in the body It would appear that some other factor is involved.

The relation of the yeast factor to the vitamin B_2 complex has also been investigated This was rendered necessary by the recent work on the dual nature of this complex and the light labile character of the flavin component It was first shown (unpublished) that in the rhesus monkey flavin was not the hæmopoietic factor which agrees with the earlier work of Groen (1935) and Ashford et al. (1936) who showed that flavin was not the extrinsic factor in pernicious anæmia. The separation of the liver and yeast hæmopoietic factors from the complement or vitamin B_4 component of the vitamin B_2 complex was next attempted by applying the method of Dakin and West (1935) for separation of anahæmin from crude liver extracts Acidulated yeast extracts which had been shown to be active in the cure of the monkey anæmia were first treated with calcium acetate and 70 per cent alcohol which removed considerable amounts of relatively inactive material The monkey hæmopoietic factor was present in the filtrate A certain amount of activity appeared to have been lost as the dose of filtrate necessary to produce a maximal response corresponded to larger amounts of dried yeast than those used in the preparation of a curative dose of the untreated extract These yeast filtrates and also the liver extract campolon were then fractionated by use of Reinecke salt which precipitates anahæmin This method in our hands gave disappointing results Thus using yeast extracts in two monkey experiments the method failed to inactivation of both soluble and insoluble fractions In a third experiment the soluble fraction, which should not contain anahæmin, was found to be active in the cure of the monkey anæmia Fractionation of campolon in the same way led to complete inactivation Similar uncertain results have been obtained by other workers attempting to separate anahæmin by the Reinecke method.

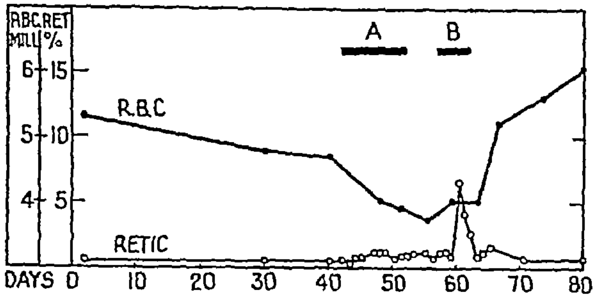

FIG 1 —Monkey No 7 Effect of treatment on red cell and reticulocyte counts
A = anahæmin (1100 mg) B = campolon (20 c cm)

Very good results were, however, obtained by using saturation with ammonium sulphate as a means of fractionation Both yeast filtrates and campolon were then separated into fractions insoluble and soluble in saturated ammonium sulphate The two fractions from campolon were tested on both men and monkeys, and those from yeast on monkeys only The insoluble fraction from campolon, which would contain any anahæmin present, induced an immediate remission in two untreated controlled cases of pernicious anæmia, whereas this fraction was completely inactive in monkeys The same monkeys subsequently responded to similar parenteral administration of the soluble fraction. Similarly the insoluble fraction from the yeast extract, which should contain any anahæmin like bodies present in yeast, was completely inactive in anæmic monkeys, who responded to treatment with the soluble fraction both fractions were in this case given by mouth. The soluble yeast fraction, unlike the soluble fraction from campolon, was inactive when given parenterally to one monkey, this animal however responded when enormous doses of new anahæmin, 200 mg daily for 10 days, were given immediately after the yeast injections

CASE REPORTS HUMAN AND MONKEY

A few illustrative cases are described, a full record will appear elsewhere

For brevity the following *abbreviations* are used Red blood cells, R B C , the figures express millions per c mm Hæmoglobin Hb figures express percentages, 100 per cent being equivalent to 14 g hæmoglobin As the red cells of the monkey are smaller than those of man, the uncorrected colour index for healthy animals is generally about 0 69, corrected for the monkey standard of 6 million red cells and 14 g hæmoglobin the colour index is approximately 0 84 In the text days are reckoned from the commencement of any one treatment

ANAHÆMIN AND CAMPOLON

MONKEY No 7 (Fig 1) was rendered anæmic by feeding deficient diet, on which he remained throughout experiment Treated with campolon in February, 1936 made a good recovery April R B C 6 495, Hb 90 per cent Relapsed July 13th, R B C 4 530, Hb 64 per cent Anahæmin parenterally 100 mg daily for 10 days 7th day R B C. 4·055, Hb 55 per cent 14th day R.B C 3 970 Hb 58 per cent Reticulocytes never above 1 per cent July 29th campolon parenterally, 4 c cm daily for 5 days 3rd day R B C 4 260, Hb 59 per cent 5th day reticulocytes 5 7 per cent 10th day R B C 4 975, Hb 70 per cent 16th day R.B C 5 590, Hb 75 per cent 24th day R B C 6 135, Hb 82 per cent No response to anahæmin, good sustained response to campolon Four other monkeys failed to respond to treatment with anahæmin, but later responded to campolon or other active extracts

CAMPOLON FRACTIONATED WITH AMMONIUM SULPHATE INSOLUBLE AND SOLUBLE FRACTIONS

MAN aged 64 (Fig 2) Uncomplicated pernicious anæmia with signs of subacute combined degeneration Histamine test meal complete achlorhydria Van den Bergh, indirect reaction 4 units Nov 10th, 1936 R B C 1 715, Hb 48 5 per cent Nov 16th R.B C 1 745, Hb 51 per cent Reticulocytes highest value 1 3 per cent Nov 17th started treatment with insoluble fraction the precipitate derived from 12 c cm original campolon given daily for 7 days and that from 6 c cm daily for 3 days Marked clinical improvement after 1st day 6th day reticulocytes reached maximum value of 30 per cent 10th day R B C 2 933 Hb 58 per cent Dose stopped 15th day R B C 3 523, Hb 72 per cent The reticulocyte peak was higher than the expected value and the red cells increased at the rate of 100,000 a day Excellent response to treatment with ammonium-sulphate insoluble fraction of campolon

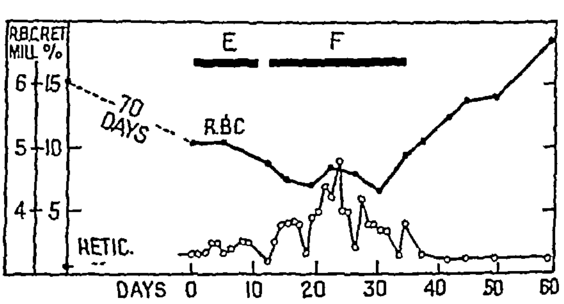

FIG 3 —Monkey No 50
E = $(NH_4)_2SO_4$ insoluble extract from 40 c cm campolon
F = $(NH_4)_2SO_4$ soluble extract from 110 c cm campolon

WOMAN aged 59 (Fig 2) Uncomplicated pernicious anæmia with signs of subacute combined degeneration Histamine test meal complete achlorhydria Van den Bergh, indirect reaction 2 units Oct 29th 1936 R B C 1 980, Hb 50 per cent Nov 2nd R B C 1 790, Hb 51 per cent Nov 9th R B C 1 700, Hb 50 per cent Reticulocytes highest value 1 8 per cent Given a single dose of the insoluble fraction, the precipitate from 4 c cm of campolon 5th day R B C 2·025 Hb 58 per cent, reticulocytes 10 0 per cent 6th day reticulocytes 18 per cent 8th day R B C 2 193 Hb 60 per cent A good reticulocyte response and a rise of 0 493 million red cells in 8 days, which though not maximal is a good rise after a single dose derived from only 4 c cm of original campolon Four more similar doses were given and on the 22nd day from the original dose the red cells had risen to 3 915, Hb 72 per cent This represents a rise of 2 2 millions in 22 days. Excellent response to treatment with ammonium sulphate-insoluble fraction of campolon.

MONKEY No 60 (Fig 3) On June 11th 1936 diet commenced R.B C 6·610 Hb 96 per cent Oct 21st R.B C 3 950 Hb 59 per cent started insoluble fraction parenterally amount derived from 4 c.cm. untreated campolon daily for 10 days. Reticulocytes maximum value 2·4 per cent 10th day: R.B C 3 605 Hb 56 per cent. Three days later as no response started treatment with soluble fraction for first 7 days daily dose derived from 4 c.cm untreated campolon; dose then increased to yield from 8 c.cm. campolon for 10 days 4th day: R.B C 3 465 Hb 57 per cent reticulocytes 3 6 per cent 8th day: reticulocytes 4·0 per cent but no rise in count so dose increased 11th day R.B C 3·610 Hb 50 per cent reticulocytes 8 3 per cent Reticulocytes remained up for further 8 days 22nd day R B C 3 700 Hb 58 per cent 27th day: R.B C 4·420 Hb 67 per cent The plateau type of reticulocyte response and slow rise in R B C count suggest that the dose was not optimal No response to treatment with ammonium sulphate insoluble fraction of campolon: suboptimal response with soluble fraction

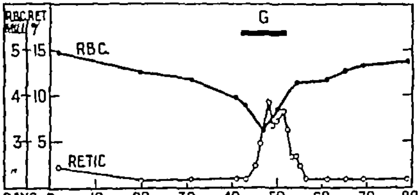

FIG. 4.—Monkey No 7
G = (NH$_4$)$_2$SO$_4$-soluble extract from 80 c.cm campolon.

MONKEY No 7 (Fig 4) On Oct 16th 1936 had been on diet for many months and used experimentally several times before R.B C 4 060 Hb 70 per cent Nov 24th R B C 3 900 Hb 57 per cent reticulocytes 0 3 per cent Nov 26th: R B C 3 760 Hb 55 per cent reticulocytes 0 2 per cent Started treatment with soluble fraction equivalent to 8 c cm original campolon 5th day: R.B C 3 230 Hb 48 per cent reticulocytes 4 7 per cent 6th day: reticulocytes 9·0 per cent and values stayed up till 10th day Dec 3rd: R B C 3·670 Hb 50 per cent 12th day: R.B C 4 270 Hb 60 per cent. 19th day: R.B C 4·44 Hb 67 per cent very few reticulocytes Good reticulocyte response and rapid initial rise in red cell count after treatment with ammonium-sulphate-soluble fraction of campolon by mouth

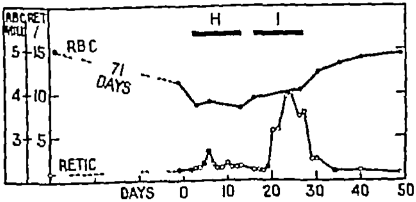

FIG. 5.—Monkey No 53
H = (NH$_4$)$_2$SO$_4$ insoluble extract from 600 g yeast.
I = (NH$_4$)$_2$SO$_4$-soluble extract from 600 g yeast.

ACIDULATED YEAST EXTRACT FRACTIONATED WITH AMMONIUM SULPHATE AFTER TREATMENT WITH (a) CALCIUM ACETATE AND 70 PER CENT ALCOHOL; (b) 80 PER CENT ALCOHOL: INSOLUBLE AND SOLUBLE FRACTIONS

Oral administration of (a)

MONKEY No 53 (Fig 5) Started deficient diet on June 12th 1936: R B C 4·675 Hb 70 per cent Oct 20th: R.B C 3 040 Hb 54 per cent Started treatment with insoluble fraction, dose derived from 60 g dried yeast given daily by mouth for 10 days No response Maximal reticulocyte value 2 7 per cent 10th day: R.B C 3 610 Hb 57 per cent Three days later as the condition was unchanged treatment was started with similar doses of the soluble fraction. 3rd day R.B C 3·610 Hb 57 per cent reticulocytes 1·6 per cent 6th and 7th days reticulocytes 9 1 per cent and 9·4 per cent respectively 10th day R.B C 3 975 Hb 61 per cent reticulocytes 7 4 per cent 17th day: R B C 4 553 Hb 67 per cent reticulocytes 0 2 per cent 23rd day: R.B C 4 745 Hb 75 per cent No response to the insoluble fraction A good reticulocyte response to soluble fraction and a steady but rather slow rise in red cells

Parenteral administration of soluble fraction from (b) followed by anahæmin

MONKEY No 62 (Fig 6) had responded to the ammonium sulphate-soluble fraction of our yeast extract so after being run out again was selected for a trial of this fraction by the parenteral route Dec 8th 1936: R B C 3 825 Hb 59 per cent. reticulocytes 0 2 per cent Dec 11th: R.B C 3 785 Hb 60 per cent reticulocytes 1 6 per cent Injections started daily dose equivalent to 50 g dry yeast for 10 days 5th day: R B C 3 510 Hb 57 per cent. reticulocytes 1·0 per cent 8th day R B C 3 200 Hb 45 per cent., reticulocytes 2·6 per cent 11th day: R.B C 2 905 Hb 40 per cent reticulocytes 1·0 per cent No response and as animal was going down rapidly treatment with anahæmin was started 200 mg daily for 10 days 7th day R B C 3 175 Hb 44 per cent reticulocytes 4 5 per cent Reticulocyte counts remained high till 10th day when value reached 10·3 per cent 11th day: R.B C 3 715 Hb 52 per cent reticulocytes 2 3 per cent 15th day: R B C 4 805 Hb 68 per cent., reticulocytes 0·5 per cent No response to parenteral administration of soluble fraction of acidulated yeast alone (active by mouth) but excellent response when enormous doses of new anahæmin were given immediately after previous treatment

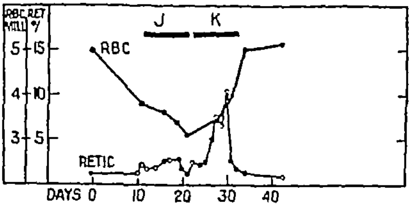

FIG 6.—Monkey No 6
J = (NH$_4$)$_2$SO$_4$-soluble extract from 600 g yeast
K = anahæmin 20 c.cm

DISCUSSION

The work described above suggests that at least two hæmopoietic factors are present in all those extracts (e.g liver autolysed yeast extracts, and wheat germ) which are active both in true pernicious anæmia in man—some only after incubation with normal gastric juice—and in the nutritional macrocytic anæmia of the monkey It is only when the principles concerned are obtained in a relatively pure form that their different action becomes clear It is not suggested that monkeys do not require the liver principle contained in anahæmin but only that the anæmia under discussion is not produced by a simple lack of this factor and cannot therefore be due solely to absence of Castle's extrinsic factor in the diet as originally suggested This monkey anæmia appears to be due in part at least, to the lack of some other factor at present unidentified It seems possible however that the two factors are concerned both in the monkey anæmia and in pernicious anæmia, and there is some evidence that this view is correct For example, the more sustained response in the monkey to the crude extracts in comparison with the response to the more highly purified fractions, even when these are given in doses derived from far larger amounts of the parent substance (yeast or liver) than those used in the preparation of the cruder extracts, points in this direction The fact that one monkey responded well to very large doses of anahæmin when given immediately after the parenteral injection of the monkey fraction from yeast also suggests that this principle is necessary for normal hæmopoiesis in the monkey The crude extracts may well contain both factors, campolon certainly does If then there is in the monkey suffering from macrocytic nutritional anæmia a deficiency of both factors, but a relatively greater lack of the new factor, then the administration of this latter may activate the small supply of the liver principle still available in the body The liver principle thus activated will cause an initial rise in the red cell count, which however will not be sustained when the small supply of the liver principle is exhausted. Accepting this explanation of the action of the new factor as correct, then there might well be exceptional cases of pernicious anæmia, in which there is a deficiency, not only in the liver principle contained in anahæmin but also in the new hæmopoietic factor Such cases would either not respond to anahæmin or make a poor unsustained response, but would respond to the cruder preparations such as campolon.

Further work is necessary to elucidate this and numerous other related problems, the most important being the relation of tropical macrocytic anæmia to the animal condition A trial of treatment with anahæmin in cases of tropical macrocytic anæmia is now being made in India

The nature of this new factor is at present unknown but is being investigated The possibility of identifying it with the vitamin B_4 fraction of the vitamin B_2 complex is suggested by the facts that it is present in the more soluble fractions of yeast, marmite, liver, and wheat-germ extracts, and that it shows similar behaviour to heat, alcohol, and various chemical reagents It is also more nearly allied chemically to the hæmopoietic substance earlier isolated by Cohn, McMeekin, and Minot (1930) than to anahæmin or hæmopoietin

CONCLUSIONS AND SUMMARY

Two factors have been separated from the liver extract campolon one soluble and one insoluble in saturated ammonium sulphate.

Given parenterally, the soluble fraction is curative in the nutritional macrocytic anæmia of rhesus monkeys The insoluble fraction, which contains the anahæmin present in campolon, is inactive in the monkey anæmia—as are also the commercial preparations of anahæmin—but is curative in pernicious anæmia

Similar fractionation of the alcohol soluble fraction of acidulated aqueous yeast extract yields two fractions, of which (when given by mouth) the insoluble is inactive and the soluble active in the monkey anæmia This soluble fraction was inactive in the treatment of one monkey when given parenterally *

There is some evidence that both factors are necessary for hæmopoiesis in man and rhesus monkeys, but that in the production and cure of the nutritional anæmia of the monkey it is the soluble fraction that is mainly concerned Its action in tropical macrocytic anæmia is being investigated

The two factors must be present in those extracts of liver, yeast, and wheat germ that are active either alone or after mixture with gastric juice in both the monkey and pernicious anæmia

The possible relationship of the new factor to the vitamin B_2 complex and to the factor previously isolated by Cohn, McMeekin, and Minot is discussed

It is a pleasure to acknowledge the generous help of Miss Harriette Chick D Sc, and her colleagues at the Lister Institute, who gave us supplies of flavin and of certain yeast and wheat-germ extracts standardised in terms of the vitamin B_4 factor We are indebted also to Dr C C Ungley of Newcastle upon Tyne for testing the anahæmin used in the present work, and to Dr Dorothy Hare and Dr Jenner Hoskin of the Royal Free Hospital for permission to treat their cases The yeast from which the extracts were made was very kindly given us by Messrs Watney, Combe and Reid of the Stag Brewery, S W 1

A detailed report of this work will appear elsewhere

The expenses were paid by a grant to one of us (L W) from the Lady Tata Memorial Trust

TUBERCULOUS LESIONS IN ASSOCIATION WITH GENITO-URINARY TUBERCULOSIS

By M C Wilkinson, M B Lond
MEDICAL SUPERINTENDENT TO THE ESSEX COUNTY COUNCIL SANATORIUM BLACK NOTLEY

It is recognised that urinary tuberculosis is secondary to a source of tuberculosis elsewhere in the body, that the prognosis depends greatly on the state of the preceding focus, and that sanatorium treatment after operation is of value in improving the prognosis (Joly 1935) It seemed to me that an investigation of the types of tuberculous lesion accompanying genito urinary tuberculosis and their effect on the disease would be of interest and would tend to confirm the hæmatogenous nature of genito urinary infections The following series was there

TABLE I —*Genito urinary and Genital Tuberculosis Classified According to Age and Sex*

Age	Genito urinary		Epid orch alone	Age	Genito urinary		Epid orch alone
	M	F			M	F	
1–10	2	1	—	41–50	4	3	1
11–20	3	1	2	51–60	2	1	—
21–30	8	2	—	Total	28	13	6
31–40	9	5	3				

M = male F = female Epid -orch = Epididymo orchitis fore investigated of unselected cases admitted to the Essex county council sanatorium during 1931–36 either from general hospitals or from tuberculosis dispensaries with the exception of 6 patients who developed genito urinary tuberculosis while under treatment at the sanatorium for bone or joint lesions The total number was 47 and they are set out according to their age and sex in Table I The number of cases with tuberculous lesions elsewhere was 29 or 62 per cent of the total. The incidence and nature of the lesions are set out in Table II

---

* Since writing the above a monkey has responded to the parenteral administration of this soluble fraction from yeast

TABLE II —*Distribution of other Tuberculous Lesions in Genito urinary Tuberculosis* (46 *Cases*)

Site and type of lesion	No of cases	Site and type of lesion	No of cases
No other tuberculous lesion	13	Both pulmonary and skeletal tuberculosis	11
Primary lung lesions or calcified hilum glands	3	Pulmonary tuberculosis and lupus	1
Calcifications in the spleen	2	Pulmonary tuberculosis and tuberculous bursitis	1
Tuberculosis of lung or pleura	7	Skeletal tuberculosis and subcutaneous tuberculous abscesses	1
Skeletal tuberculosis	8		

In estimating the effect of these other lesions on the severity of the disease the time that has elapsed since discharge has generally been too short for opinion to be of value. The factors that have been used for this purpose therefore are the mortality rate of patients in each group of extraneous lesions, the present condition in each group of the patients who are still alive and the average duration of the disease of these patients These particulars are given in brief in Table III

TABLE III —*Present Condition*

Distribution of lesions	No of cases	Alive	Average duration (yrs.)	Present condition Satis	Present condition Not satis	Still under treatment	No recent information	T B in urine	No T B in urine	Dead
Genito urinary tuberculosis alone	18	16	6	10	5	1	0		11	2
With lung tuberculosis	7	5	2–3	3	1	1	0	2	3	2
With skeletal tuberculosis	8	7	1–5	1	3		1	6	1	1
With lung and skeletal tuberculosis	11	7	2–5	2		2	1	3	3	4
With lung and other tuberculous lesions	2	1	5	1	0	0	0	0	1	1
With skeletal and and other tuberculous lesions	1	1	3	1	0	0	0	0	1	0
Total	47	3	—	18	11	6	2	15	20	10

Present condition satis. = Health good and no marked symptoms

Present condition not satis = Health poor or marked symptoms present

WITHOUT TUBERCULOUS LESIONS ELSEWHERE

In the series 18 cases had no other discoverable tuberculous lesions than the genito-urinary except in 3 cases with evidence of primary infection and in 2 cases with calcified miliary foci in the spleen The presence of miliary splenic foci may be regarded as evidence that a bacillæmia had previously occurred Miliary tubercles may be observed by radiography to disappear from the lungs of children without leaving evidence in the form of calcifications and a bacillæmia may therefore have occurred also in other cases of this series without leaving any traces that could be detected radiographically In this group of 18 cases, however the resistance of the patient was good and the disease whatever its method of dissemination became fixed in one system genital or renal or even in one focus It thus became amenable to removal by excision. In examining this group of cases therefore it would be expected that operative treatment had been performed in the majority and that the results were good This is confirmed by the findings

Of the 18 cases 16 are alive after an average period of more than six years from the date of onset of symptoms 2 of these were of genital tuberculosis only treated by orchidectomy while the remaining 14 cases had renal tuberculosis 10 of which had been treated by nephrectomy Of the 2 patients who died 1 had been treated by nephrectomy 15 years previously the other was a child who had had no operative treatment

The health of the majority of the survivors at the present time is satisfactory

WITH TUBERCULOSIS OF THE LUNG OR PLEURA

Tuberculous pulmonary lesions were found in 20 cases of the 47 (42 5 per cent,) but as the earlier cases in the series did not have routine chest radiograms this figure is probably an under statement It may be compared with the figure quoted by Reisner (1934) who in a series of 69 cases of genito urinary tuberculosis in New York found pulmonary lesions in 44 (66 per cent) Reisner has made observations on the types of lung lesions occurring with extra pulmonary tuberculosis and has classified them into two main groups In the first and larger group the disease is bilateral is distributed in an apico-caudate direction is frequently non ulcerative and causes no abnormal physical signs The lesions of the second group are those characteristic of phthisis. In the first group in Reisner's opinion the disease is hæmatogenous in origin The finding in the present series tend to agree with Reisner's and are given in Table IV so far as is possible according to his classification The mortality with each type of lung lesion is also noted From this Table it will be seen that the apical lesions which are usually of a low degree of activity make little difference to the severity of the disease; that the fibrocaseous lesions of phthisis have not been of grave prognosis; and that the bilateral apico caudate lesions have proved the most dangerous The latter are usually an advanced stage of the bilateral apical lesions but an advance of the disease of this sort is not likely when once the apical lesions have become fibrotic The 2 cases of miliary tuberculosis mentioned in this series were ones in which the disease was discovered radiographically There is no doubt that there may have been other cases also in the series that died of miliary tuberculosis

TABLE IV —*Classification of the Tuberculous Lung Lesions*

Type of lesion	No of cases	Alive	Dead
Bilateral apical lesions, interstitial or fibrotic activity nil or slight	8		1
Unilateral apical scarring	1	1	0
Widespread bilateral apico-caudate lesions	3	0	3
Bilateral acute disseminated disease of miliary type		0	2
Fibrocaseous lesions of phthisis	3	2	1
Pleural effusions	3	2	1 (child)

A consideration of the effect of tuberculous lung lesions on renal disease in this series is complicated by the presence of additional tuberculous lesions in the skeleton or other tissues in 13 of the cases These additional lesions increase the gravity of the disease Thus 7 cases had tuberculous lesions in the lungs, of whom 5 are alive Of the 13 patients who had skeletal and other lesions in addition to lung lesions, 5 have died, the average duration of the disease of the 8 cases alive is only 2¼ years, but the fact that some of these are making favourable progress is an indication that with sanatorium treatment even cases with multiple lesions may occasionally do well, provided operation has been practicable It will be seen, however, that the resistance of the patients in this group with lung lesions is lower than in the previous group in which there were no tuberculous lesions outside the genito urinary tract It will be seen also that when there are multiple tuberculous lesions, the lung lesions tend to be of the more serious type

WITH TUBERCULOSIS OF THE SKELETAL SYSTEM

There were tuberculous lesions in the skeleton in 20 cases (42 5 per cent) In 8 the lesions were quiescent and in 12 active The quiescence or activity of the lesions, however, was found to be less important than their accompaniment by pulmonary lesions Thus 5 of the 8 cases with quiescent skeletal lesions are alive and 3 have died, and 10 of the patients who had active skeletal disease are alive and 2 have died On the other hand, when the groups of skeletal lesions are considered that occurred with and without pulmonary disease it is found that the presence of pulmonary disease is significant There were 9 cases with no pulmonary involvement of these 8 are alive and 1 has died, there were 11 cases of skeletal disease with pulmonary involvement, of whom 7 are alive and 4 have died

In every case the skeletal lesion preceded the lesion in the genito urinary tract, but it is not possible to ascertain whether the latter was the result of invasion of tubercle bacilli from the skeletal lesion into the blood stream, or whether there had been an infection from another source The situations of the skeletal lesions were as follows in 8 cases the lesions were in the spine, in 5 in the hip, in 2 in the sacro iliac joint, and in single cases in the shoulder, sternum, knee, rib, and wrist Several patients had multiple skeletal lesions The variety of the sites of skeletal disease and the incidence of genito urinary lesions in this group indicate that these lesions were of hæmatogenous origin

URINARY TUBERCULOSIS WITH TUBERCULOSIS OF THE LYMPHATIC SYSTEM

In childhood the lymphatic system forms a barrier to invasions of the blood stream by tubercle bacilli genito urinary tuberculosis is therefore fortunately uncommon among children It becomes more common in later life, when the lymphatic tissues of the body begin to atrophy It is therefore not surprising in this series to find very little evidence of tuberculous involvement of the lymphatics In 3 of the children there was evidence of primary infection with calcified hilum glands In 3 cases also calcified tuberculous glands were present in the abdomen and in 1 case there were healed cervical glands In no patient was active glandular tuberculosis present

TUBERCULOUS EPIDIDYMO ORCHITIS WITH LESIONS OUTSIDE THE GENITAL OR URINARY TRACTS

In this series of cases it is worth noting that genital tuberculous lesions, occurring without renal tuberculosis, were associated with hæmatogenous tuberculous lesions outside the genital or urinary tracts In 20 cases of epididymo orchitis the relationship with renal disease was as follows —

(1) Cases in which no renal disease has developed	6
(2) Cases in which epididymo orchitis preceded renal disease	8
(3) Cases in which epididymo-orchitis followed renal disease	3
(4) Case in which the onset of epididymo orchitis and renal disease was concomitant	1
(5) Cases in which the history of precedence was doubtful	2

In 15 cases, therefore, detectable renal disease did not precede epididymo orchitis, and infection of the epididymis could not have occurred by lymphatic spread from the kidney Of these 15 cases 11 were preceded or accompanied by lesions of hæmatogenous origin outside the genital or renal tracts From this it may be inferred that genital tuberculosis, like renal tuberculosis, is part of a hæmatogenous infection and is not a primary manifestation of tuberculous disease The incidence of genital with renal tuberculosis does not seem to have increased the severity of the disease in this series

I wish to express my gratitude to Dr W A Bullough, medical officer of health to the Essex County Council and to Mr R Reid consulting surgeon to the sanatorium, for the assistance they have given me with this article, and to the tuberculosis officers of the Essex County Council for the records that they have provided of the present condition of the cases in the series

GENITO-URINARY TUBERCULOSIS

WITH A REVIEW OF 100 CASES

By Frank Harvey, F R C S Edin
CONSULTING SURGEON TO ST ANTHONY'S HOSPITAL, CHEAM TO ST MICHAEL'S HOSPITAL HAYLE AND TO BROADMOOR CRIMINAL LUNATIC ASYLUM

The term genito urinary tuberculosis comprises tuberculous disease of the kidneys, ureters, bladder, prostate, vesicles, testes, and epididymes in the male, and of the uterus, ovaries, Fallopian tubes, vagina, and vulva in the female The condition is never primary, but is secondary to a tuberculous lesion elsewhere, which may be apparently quiescent This lesion is either primary (e g, in the lungs) or secondary (e g, in bones) Harris (1928–29) found that of 110 cases of tuberculosis of bones a quarter had tubercle bacilli in the urine And Medlar (1928) states that tuberculous bacilluria never occurs without demonstrable lesions in the kidneys, though these are often only microscopic in size Secondary infection by pyogenic organisms is common, and tuberculosis often supervenes on chronic pyogenic infections

The genito urinary disease may be part of a generalised miliary tuberculosis (tuberculous septicæmia) or (as in the 100 cases on which this paper is based) it may be localised to one or more organs

Local Pathology

Kidney —Renal tuberculosis is generally unilateral, later involving the ureter and bladder, but the second kidney may become infected through the blood stream through the peri ureteral lymphatics or by reflux of urine from the bladder Grey tubercles form usually in the apex of the pyramids but sometimes around the glomeruli in the cortex and they gradually coalesce to form a caseous mass which either calcifies or breaks down to form an abscess. In either case the result may be involvement of the whole kidney or a localised calcified mass or an abscess Where the kidney is converted into a large tuberculous abscess the perinephric fat is usually infected More rarely the kidney becomes fibrosed and contracted

Ureter—In serious cases the ureter is converted into a rigid tube with thick walls the mucous coat being destroyed over large areas

The *bladder* is always infected either from the kidneys, from the prostate and vesicles or (in the female) from the urethra In the early stages of infection from the kidney there may be only a few grey tubercles situated around one or both ureteric orifices with some associated œdema and redness later there is ulceration and the ureteric orifice becomes rigid (golf hole type) When the bladder is infected from the prostate and vesicles or from the urethra the trigone is first affected In tuberculous disease of the bladder the mucous membrane soon becomes acutely inflamed cystoscopy is difficult and the bladder capacity is greatly reduced The ulcers are characteristic being small and round with undermined edges and tend to become confluent the base is sloughy Secondary pyogenic infection is common

In my own series tuberculosis has rarely spread *from bladder to genital organs*, but often in the male in the opposite direction

MALE ORGANS

Epididymis—The tuberculous infection begins in either globus major or minor It is usually unilateral and due to spread from the prostate but it can be hæmatogenous The epididymis may become converted into a caseous mass or the disease may be limited to a nodule which becomes calcified At first there is an associated hydrocele—more rarely a hæmatocele Suppuration is common with involvement of the testes and scrotum leading to sinus formation with secondary infection

The *testis* is involved by spread from the epididymis.

The *vas deferens* is infected either from the prostate and vesicles or from the epididymis It may become enormously thickened

Tuberculosis in the *prostate* comes from the epididymis (via the vas deferens), from the blood stream or more rarely from the bladder as a result of severe ulceration involving the internal urinary meatus The lesion is usually caseous but occasionally it is sclerotic producing contraction of the prostatic urethra with retention of urine In favourable cases calcification occurs Abscess formation is not uncommon; the pus may track alongside the rectum into the perineum producing an ischiorectal abscess or may perforate the bowel and cause a urinary fistula More often it bursts into the bladder

Seminal vesicles—Vesiculitis is due to spread from the epididymis or prostate and the outline of the vesicles can be seen on cystoscopy

FEMALE ORGANS

Norris (1933) states that tubercle bacilli may infect the female genitalia (1) through the blood stream—the commonest route (2) by direct extension from a neighbouring focus such as the peritoneum or intestinal or urinary tracts (3) from a nearby focus via the lymphatics or rarely (4) by direct infection as by tubercle bacilli in the semen with slight trauma or by infected instruments

In the *external genitalia* the disease may be either ulcerative or hypertrophic the former being the commoner The hypertrophic often becomes ulcerative and tubercle bacilli are more easily found in the ulcerative type

Vulva—Vestibular tuberculosis is usually of the small multiple ulcer variety but a papilliferous or hypertrophic condition is also seen

Bartholin s glands are infected occasionally without any other lesion of the vulva

In the *vagina* tuberculosis is rare the usual form consists of small multiple ulcers and it is usually due to spread from the uterus

The *cervix* is also rarely affected. There may be a shallow indolent ulcer with thin undermined edges and irregular base or the condition may resemble carcinoma (hypertrophic form).

Uterus—The body of the uterus is fairly often the site of tuberculous disease manifested either as endometritis or perimetritis, the first being the commoner There is often a pre-existing tuberculous salpingitis, and the endometrium is involved around the tubal openings The miliary type is more often met than the ulcerative or the caseous

Fallopian tubes—Chronic inflammation due to puerperal sepsis or gonorrhœa is an important predisposing factor In more than three quarters of Norris s cases the primary lesion was pulmonary

The *ovaries* are resistant to tuberculous disease *and when present it has usually spread from the tubes* or from the peritoneum The natural process of arrest is by fibrosis and calcification

Diagnosis

Of the 100 cases under review which came from London the Home Counties, and Cornwall 7 had a history of pleurisy and 1 of tuberculous enteritis Otherwise *no tuberculous history was given In only* 17 could any clinical or radiological evidence of extragenital tuberculosis be discovered the distribution being as follows; lungs 4; glands of neck 3 spine 2 sacro iliac joints 1 hip 4 carpus 1 tarsus 1 peritoneum 1

In *renal disease* dysuria was the first symptom in 37 of the 40 cases in the other 12 it was symptomless hæmaturia Cystoscopy was not done on patients who had to pass urine more than once an hour nor in cases with strangury The diagnosis was established by finding tubercle bacilli either by ureteric catheterisation or by sedimentation of a 24 hours specimen of urine with inoculation of a guinea pig if necessary Of 20 cases investigated pathologically however 14 (70 per cent) showed no tubercle bacilli at all the organisms in the other 6 being all of human as opposed *to bovine type*

Pyelography intravenous and ascending showed deficient filling of the pelvis and calyces the latter being clubbed ; while intravenous pyelography had the additional advantage that the rate of excretion of the dye gave an idea of the severity of the lesion

Male genital tuberculosis—The commonest first indication of epididymitis is a painless enlargement More rarely an acute form is seen with pain and an associated hydrocele The nodular feel of the epididymis and the fact that testicular sensation is retained help to differentiate tuberculosis from syphilis In the acute variety aspiration of the hydrocele permits of more accurate palpation Also, rectal examination will often reveal nodules in the prostate

In tuberculous *prostatitis there may be no symptoms* other than occasional dysuria, with slight discharge, which "gums" the external urinary meatus Examination of the urine reveals shreds and pus, and tubercle bacilli On the other hand a perineal abscess is occasionally the first symptom, or, more rarely, hæmaturia In tuberculous epididymitis, rectal examination more often than not reveals prostatic nodules

Female genital tuberculosis may be very difficult to diagnose Vulvitis, infection of Bartholin's gland, and cervicitis cannot be reckoned tuberculous unless tubercle bacilli are found, tuberculous disease of the cervix may simulate carcinoma, while tuberculous vulvitis may simulate syphilis The discharge from a tuberculous endometritis is usually less offensive and hæmorrhagic than that of malignant disease, but the presence of tubercle bacilli in the endometrium is the only sure method of diagnosis, and it necessitates curettage Tuberculous disease of the Fallopian tubes may be suspected if the patient is suffering from tuberculous disease elsewhere, but otherwise it can only be made at operation

The 100 Cases

Of the 100 cases here described all but 8 were seen and treated at St Michael's Hospital, Hayle, Cornwall Some had already been operated on, some were sent for observation and treatment, while some were sent because they were inoperable but improved to such an extent that operation became feasible The youngest was 14 years of age (female) and the oldest 60 (male), the average being 25½ years There were 52 males and 48 femals The history sheets which came with most of the patients contained a note of the home conditions which were described as good in 24 cases, fair in 25, and bad in 51 These unsatisfactory conditions made it difficult to secure even moderately suitable after care

The *condition on admission* may be briefly summarised as follows —

Febrile	4	General condition—	
Sinuses	17	Fair	64
Operation scars	24	Bad	36

In considering the results the following classification was adopted —

Arrested or "cured" means that there were no signs or symptoms and the urine was clear

Relieved means that weight had increased signs and symptoms were less pronounced, there was no fever or pain, and the urine contained no more than a trace of pus

The following Table shows the position at the end of the five years It will be noted that there were 9 deaths amongst the renal cases, in the 4 cases not operated on the condition was bilateral The cause of death was uræmia in 3 cases and generalised tuberculosis in the remaining 6 Of the 6 males with genital tuberculosis who died 4 developed bilateral renal disease with gross cystitis and uræmia, the other 2 died of pulmonary tuberculosis None of the 4 patients with tuberculosis of the prostate developed epididymitis, but 1 had severe cystitis, and was worse when last examined than on admission

Treatment

Genito urinary tuberculosis is treated on the same principles as tuberculosis elsewhere Good hygiene, a generous diet (unless there is fever), fresh air and sunlight, and a cheerful environment are necessary Febrile patients are kept in bed, and so are those with extensive sinuses, for a sinus will never heal if the part affected is not kept at rest Afebrile patients are allowed moderate exercise In renal tuberculosis plenty of liquids (e g, barley water, Imperial drink, water, tea, and milk) are given, for they alleviate dysuria Extra milk has been found very helpful

Results after Five Years or More

—	Arrested or 'cured'		Relieved		Worse		Deaths		Untraced.		Totals
	Op	Non op	Op	Non op	Op	Non op	Op	Non op	Op	Non op

* Tuberculous endometritis treated by X ray therapy
† Infection of Bartholin's gland Primary infection pulmonary

The immediate reaction to treatment was in most cases remarkably good, the patients put on weight with a feeling of improved health, but symptoms such as dysuria were not so quickly relieved

Heliotherapy, if it is to expedite recovery, has to be carefully graduated Too reckless exposure to the sun's rays generally produces ill results—blistering, pyrexia, and a mild degree of sunstroke

The results from tuberculin treatment (T R) have been disappointing Ten cases were given tuberculin for six months, and at the same time a similar number, apparently in the same stage of the disease were treated without it The cases treated with tuberculin did not progress so favourably as those without, they often became pyrexial with increase of symptoms

Dysuria is difficult to relieve in severe cases of renal tuberculosis, and may demand irrigation of the bladder with boric lotion, or instillation of a solution of silver nitrate (1 in 10,000) or of flavine in glycerin (1 in 1000) Iodoform emulsion has proved beneficial in ulcerative cystitis and diathermy has helped to clear up chronic ulceration Sandal-wood oil capsules are often effective, and a mixture of potassium citrate, tincture of hyoscyamus, and belladonna gives relief Where a nephrectomy has been performed, the continuance of dysuria is usually due to disease of the lower end of the ureter on the affected side, and ureterectomy sometimes becomes necessary Dysuria due to tuberculous prostatitis is the most intractable form, and in severe cases the patient becomes incontinent, with an œdematous external urinary meatus In uncircumcised patients the prepuce becomes chronically inflamed, with multiple fissures The application of medicinal paraffin to the prepuce affords some relief

For *operative treatment* to be successful in renal cases, early diagnosis is essential In three cases intravenous urography showed that the disease was chiefly localised to one kidney and nephrectomy was performed with success The removal of a calcified kidney is not in my opinion warranted unless there are definite indications that an abscess is forming This applies, I think to all dead tubercle since operative treatment is liable to light up the disease and produce a generalised tuberculosis

Orchidectomy was performed in cases where there were sinuses and the testes and epididymis had been converted into abscess cavities. Epididymectomy has not been used and of the two patients on whom this operation was performed before admission to St Michael s Hospital one has died from pulmonary tuberculosis and the other cannot be traced and is presumably dead

In cases of tuberculosis of the prostate no operation other than the opening of abscesses pointing in the perineum has been attempted One patient is still under treatment who has had three perineal abscesses incised and drained On admission he was suffering from a rectovesical fistula complicated by a left ischiorectal abscess and left epididymitis with abscess formation which necessitated orchidectomy

Summary and Conclusions

Of 100 cases of genito urinary tuberculosis reviewed after five years 15 are dead and 19 untraced If the latter are presumed to be dead the total death rate is 34 per cent What is known as sanatorium treatment is essential for this disease and at least 12 months treatment is required with suitable after care Operation on dead or quiescent tuberculous foci is inadvisable

THE EFFECT OF AN ANTI-VI BACTERIOPHAGE ON TYPHOID INFECTION IN MICE

By I N Asheshov Joyce Wilson
and W W C Topley

(From the London School of Hygiene and Tropical Medicine)

Many attempts have been made to study the influence of different strains of bacteriophage on experimental infections in laboratory animals Two of us (W W C T and J W) have previously recorded studies on the effect of phages active against *Bact typhi murium* (*Bact aertrycke*) in experimental mouse typhoid both as it occurs in individual mice and in the form of experimental epidemics These studies and the results published by many other workers have recently been summarised in a report issued by the Medical Research Council (Greenwood et al 1936) and there is no need to review the literature here It will be sufficient to note that no satisfactory evidence has yet been obtained that a phage exerts any significant effect on the course of an experimental infection In the report in question the present position was summed up as follows

Although all the present indications are definitely against the efficacy of this agent in vivo except perhaps in cholera and although the argument of inadequate virulence or insufficient polyvalency of the phage employed cannot be accepted a a satisfactory explanation of an unlimited number of negative results we do not think that this field has yet been explored to the point at which further search becomes useless It is at least far more likely that clear and definite answers favourable or unfavourable will be obtained by controlled animal experiment than by any relatively uncontrolled trial in the field The present paper deals with certain experiments that we have recently carried out along these lines

Our earlier trials formed an extension of our previous studies on the action of various phages in mouse typhoid. Certain of these results were more promising than any that we had formerly obtained but they were irregular and not always repeatable and it was clear that many different factors were involved. It was far easier to induce delay in the time to death than to protect mice against a fatal attack of this particular infection It seemed desirable to test the effect of a phage on an infection of a type that in normal animals leads either to rapid death or to recovery and the isolation by Sertić and Boulgakov (1936) and more recently by other workers of a phage active against Vi strains of *Bact typhosum* offered an opportunity of carrying out experiments on an infection of this type

Experimental

The strain of phage used in these experiments was supplied to us by Drs Sertić and Boulgakov and the Vi strain of *Bact typhosum* was the Rejuvenated Rawlings strain for which we are indebted to Major General Marrian Perry of the Royal Army Medical College To each we should wish to express our thanks

In the first experiment mice in batches of 30 were injected intraperitoneally with a mixture containing 1 5 × 10^9 phage particles and 100 10^6 *Bact typhosum* in 0 5 c cm of Ringer s solution The mixtures were allowed to stand at room temperature for approximately ten minutes before inoculation The phages tested in this experiment were the pure anti Vi phage supplied by Dr Sertić (S/Vi) another pure phage supplied by Dr Sertić that was active against both the O and the Vi forms of *Bact typhosum* (S/O Vi), a crude mixed phage isolated by one of us (I N A) *from sewage* containing an anti Vi phage (A/Vi crude) and a mixture of the pure phages S/Vi and S/O Vi As controls 30 mice were injected with a mixture of heat killed S Vi phage and *Bact typhosum* and two batches of 30 mice were injected with *Bact typhosum* alone All mice were observed for 7 days It may be noted that the pure S/Vi phage and the crude A/Vi phage produced more rapid lysis in vitro with less secondary growth, than the non-specific S/O Vi phage

The results are set out in Table I It is clear that under these conditions the living anti Vi phage is a very effective protective agent while the non specific phage has no protective effect The heat killed anti Vi phage has no significant action All further experiments were carried out with the S Vi phage

It is obvious that the conditions of this experiment which has been repeated with the same results are particularly favourable to the phage since it had an opportunity of uniting with the bacteria in vitro before the mixtures were injected into mice In order to determine whether a similar protective effect would be exerted when the phage encountered the bacteria in the tissues we injected the phage intravenously and the living bacteria intraperitoneally the second series of injection 1 2 performed about 45 minutes after the first The doses of phage and bacteria were the same in this experiment as in the preceding A control group received an intravenous injection of heat-killed phage before the intraperitoneal injection of living typhoid bacilli, and a second control group received no phage

TABLE I

Showing the effect of an anti Vi and other phages on the intraperitoneal infection of mice with a Vi strain of Bact typhosum *Phage (1 5 × 10^9 particles) and bacteria (1 × 10^9) being mixed before injection*

Phage	No of mice tested	No of mice dying
S/Vi	30	0
A/Vi crude	30	2
S/O Vi	30	25
S/Vi + S/O Vi	30	1
S/Vi (heated)	30	24
None (control)	30	22
None (control)	30	23

The results are set out in Table II It is clear that the anti-Vi phage is able to exert its protective action when it meets the bacteria in the tissues

The next step was clearly to determine whether the phage had any curative action—i e , whether it would exert a protective effect when administered *after* the injection of living typhoid bacilli In this experiment the bacilli were injected intraperitoneally into five groups, each of 30 mice The first group received an intravenous injection of living phage immediately after the intraperitoneal injection of bacilli The second group were injected with phage after 2 hours, the third group after 4 hours A fourth group received an intravenous injection of heat killed phage immediately after the intraperitoneal injection of bacilli A fifth group received no further treatment These last two groups served as controls

TABLE II

Showing the effect of the intravenous injection of an anti Vi phage immediately before the intraperitoneal injection of a Vi strain of Bact typhosum

Phage injected	No of mice tested	No of mice dying
S/Vi	30	3
S/Vi (heated)	30	25
None (control)	30	26

TABLE III

Showing the effect of administering anti Vi phage intravenously at varying periods after the intraperitoneal injection of a Vi strain of Bact typhosum

Phage injected	Time after injection of bacilli	No of mice tested	No of mice dying
S/Vi	At once	30	3
S/Vi	2 hours	30	11
S/Vi	4 hours	30	23
S/Vi (heated)	At once	30	27
None (control)	—	30	30

In this experiment the dose of phage was the same as before but the dose of typhoid bacilli was increased to 250 × 10^6

The results are set out in Table III The anti-Vi phage has as great a protective action when injected intravenously immediately *after* the intraperitoneal injection of living typhoid bacilli as when injected immediately *before* (Table II) If the intravenous injection of phage is delayed for 2 hours after the injection of bacilli there is still a significant protective effect , but it is considerably reduced If the injection of phage is delayed for 4 hours its protective action becomes insignificant In this connexion it must be remembered that the course of this infection in mice is extremely acute In this experiment, 23 and 27 of the 30 mice in the two control groups were dead within 24 hours

Discussion

Typhoid infection in the mouse is a highly artificial disease The lethal dose of bacilli, even with a virulent Vi strain, is relatively large, and toxæmic effects are marked at an early stage of a fatal infection We should not therefore be inclined to argue too readily from the results of these experiments to infections of a more typically invasive type

We think, however, that one problem has been decisively answered A phage may be active in vivo as well as in vitro , and, under suitable conditions, a phage that has a specific action on the surface antigen of a virulent bacterium is capable of exerting a significant protective action when it meets that bacterium in the tissues

In view of these findings it is clearly desirable to examine very carefully the possibility that a similar protective action may be exerted in acute or sub acute infection of the typically invasive type, if the conditions are correctly adjusted

Two of us (I N A and J W) are receiving research grants from the Medical Research Council who are also contributing to the expenses of this investigation

ŒSTRADIOL BENZOATE THERAPY IN DEPRESSIONS AT THE MENOPAUSE

BY M S JONES, M B , M R C P Edin , D P M
WALTER SMITH KAY RESEARCH FELLOW EDINBURGH UNIVERSITY

T N MACGREGOR M B , F R C S Edin , M C O G
CRICHTON RESEARCH SCHOLAR AND CLINICAL TUTOR IN GYNÆCOLOGY ROYAL INFIRMARY EDINBURGH AND

H TOD, B Sc , Ph D
BIOCHEMIST ROYAL EDINBURGH HOSPITAL

(From the Royal Edinburgh Hospital for Mental and Nervous Disorders, and the Institute of Animal Genetics, Edinburgh University)

THERE is at present a reactionary tendency to minimise the importance of the climacteric in the production of psychotic or neurotic breakdowns It is possible that the pendulum has swung too far and that research into female sex physiology by modern methods might shed light on these disorders We accordingly decided to investigate and treat a series of patients along endocrinological lines

Seventeen cases were chosen in which the onset of the depressive illness coincided with the onset of the menopause, as judged by the history given As the endocrine imbalance at the menopause is associated with abeyance of ovarian function, substitution therapy with œstradiol benzoate was instituted Unfortunately it was necessary to include in our series several patients who had been in hospital for some years before the therapy was started , and the same shortage of clinical material made it impossible to use similar cases as controls The psychiatric picture varied naturally with each individual case but all showed definite depression without retardation agitation partial or complete loss of interest in their surroundings, and insomnia, while in most of them suicidal ideas were expressed A careful physical examination was made in all.

Before treatment with œstradiol benzoate a 24-hour specimen of urine was examined quantitatively for œstrin and gonadotropic hormone In the few cases where the patient was still menstruating an attempt was made to obtain the urine immediately before the onset of menstruation A glucose tolerance curve was also done. Each patient was then given injections of 5 mg œstradiol benzoate twice weekly unless she was menstruating The total amounts given varied from 60 to 140 mg On the cessation of treatment the glucose-tolerance test and the quantitative estimation of gonadotropic hormone were repeated

RESULTS OF TREATMENT

Of the 17 patients treated 6 made a satisfactory recovery as judged by their ability to return to their former occupation and these have all remained well for at least three months (Table I) It is interesting to note that the average stay in hospital of these 6 patients after treatment began was three months the extremes being two and five month whereas an illness of this kind usually lasts at least nine months Of the remaining 11 patients 5 are still in hospital and 6 have been discharged though still far from well. These cases were in most instances less satisfactory therapeutic propositions than those that were successfully treated in 2 of them the diagnosis was in doubt and later development suggested that they belonged to the paranoid rather than the depressive group while in several of the others the patients had been in hospital as long as four years before œstradiol benzoate therapy was attempted

TABLE I

Duration of Illness and Result of Treatment

Case.	Age.	Duration of psychosis before treatment (months)	Time since last menstrual period (months)	Result
1	52	12	M	Good
2	37	6	M	
3	44	24	24	Unsatisfactory
4	47	4	15	
5	62	15	3	
6	40	48	M	
7	46	6	M	Good
8	49	13	M	Unsatisfactory
9	41	48	7	
10	48	12	M	
11	50	6	30	
12	48	12	1	
13	53	24	24	
14	38	3	3	
15	50	10	3	Good
16	41	18	30	
17	45	30	3	

M = still menstruating

Œstrin in measurable quantities was present in the urine in 4 of the 13 cases tested but only in very small amounts In 2 of these cases gonadotropic hormone quantitatively amounted to more than 50 mouse units (M U) per litre of urine and in the other 2 it was less than 50 M U (Table II) These 4 patients were all menstruating Two others whose urine contained no measurable quantity of œstrin were also menstruating These 6 cases in which menstruation was still going on all showed flushings and other indications of *œstrin insufficiency*

Of the 13 cases in which gonadotropic estimations were done before and after treatment 11 gave at the start a gonadotropic finding of more than 50 M U per litre, and this was altered after treatment to less than 50 M U In the remaining 2 cases the results before and after treatment were both less than 50 M.U In 8 cases the glucose tolerance curve after treatment was substantially lower than before treatment This inhibition *was found in all the cases in which* the patient recovered In all cases somatic symptoms such as flushings and backache which were present before treatment were abolished by œstradiol benzoate

TABLE II

Hormones in Urine Before and After Treatment and Dose of Œstradiol Benzoate (Dimenformon) Given

Case	Œstrin in urine before treatment (M U per 24 hours)	Gonadotropic hormone		Total œstradiol benzoate (mg)
		Before treatment	After treatment	
1	0–10	+	–	120
2	10–20	–	–	80

16	*Less than 10*	+	–	100
17		+	–	75

Gonadotropic hormone + = more than 50 M U per litre of urine
– = less

DISCUSSION

Frank and Salmon (1935) demonstrated that complete inhibition of the gonadotropic hormone of the anterior pituitary could be produced in menopausal women by administering œstrin. The inhibitory effect was not permanent and gonadotropic hormone was again found in the urine in measurable quantities 28–70 days after the cessation of œstrin injections. In our series the excretion of gonadotropic hormone was inhibited in all cases in which there was an initial excess of hormone The lowering of the sugar tolerance curve which was noted in our cases as in those of McCowan and Quastel (1931a and b) was probably due to the improvement in the emotional and physical state

The results we have obtained substantially agree with those of Werner and others (1934 1936) and of Bowman and Bender (1932) both of whom regard œstrin as having a definite effect in accelerating recovery in uncomplicated cases of involutional melancholia Jones and MacGregor (1936) have shown that excessive excretion of gonadotropic hormone may be found many years after the menopause and that its inhibition with œstrin therapy does not affect the clinical picture Possibly however the hormonal disturbances of the menopause can sometimes be readjusted temporarily by œstradiol benzoate therapy and thus tide the patients over the crucial period The division between the post menopausal syndrome (hot flushes irritability &c) and complete mental breakdown is not well defined and for the relief of the minor symptoms œstrin is usually effective

SUMMARY

1 Seventeen cases of depression occurring at the menopause were treated with twice weekly injections of 5 mg œstradiol benzoate The total amount given varied from 60 to 140 mg

2 Six of the patients made a good recovery within five months and have resumed their normal lives The somatic symptoms were relieved in all the patients who had them

3 In eleven cases showing excessive amounts of gonadotropic hormone in the urine œstradiol benzoate reduced the amount excreted.

We are indebted to Prof D K Henderson, physician superintendent of the Royal Hospital for Nervous and Mental Disorders, for clinical facilities, and to Prof F A E Crew for the opportunity of performing the hormone tests in his department We also wish to thank the Organon Laboratories for a generous supply of œstradiol benzoate (Dimenformon)

The expenses of this investigation were defrayed by a personal grant to H T and an expenses grant to T N M from the Medical Research Council

CLINICAL AND LABORATORY NOTES

CONGENITAL SYPHILIS IN A MONOVULAR TWIN

By L S PENROSE, M.D Camb
RESEARCH MEDICAL OFFICER ROYAL EASTERN COUNTIES INSTITUTION COLCHESTER

TWINS who are unequally affected by congenital syphilis have been recorded by Haslund (1924) and Dennie (1924) In all but one instance the twin pair has been considered binovular, cases have also been reported in which monovular twins are equally affected These observations lend support to the view that differences in hereditary constitution may determine susceptibility to the congenital infection Against this view we have the evidence of Dennie's case of twins, judged to be monovular, one of whom had marked signs of congenital syphilis and the other had no such signs Unfortunately the diagnosis that the twins were monovular was not supported by an specific tests

The present communication records another pair of twins who appear to be monovular and unequally affected

Two female children, K A and V A were born on July 31st 1922 The father, then aged 33, was a casual labourer, usually out of work, who had been sent to prison for ill treating a dog and neglecting his children His mental grade was such that he could probably have been certified feeble minded He died in 1933 with cancer of the throat The mother was aged 30 in 1922, she is of low mentality, was sent to prison with her husband for neglecting the children, and is generally known to be an immoral character Physically she is a poor specimen There were four pregnancies An illegitimate male was stillborn in 1920 The twins were born in 1922 A boy, born in 1924, is an imbecile whose Stanford Binet score, at the age of 10 years 2 months, was 4 years 4 months He shows no signs of syphilis, and a Wassermann test was negative A girl, born in 1925, tested at the age of 8 years 4 months had a Stanford Binet score of 6 years and can be regarded as almost feeble minded She is physically healthy

K A, aged 12 years 8 months is physically a poor specimen with a sallow complexion round shoulders, and flat feet She talks clearly and sensibly, can play whist, and likes skipping, her Binet mental age is 6 years 4 months and she is certified feeble minded The blood Wassermann reaction is negative

V A was aged 11 years 11 months when she came under observation after having been certified an idiot Her Binet mental age was found to be 2 years 4 months Her speech was very defective hearing good She had conspicuous signs of congenital syphilis the incisor teeth showed irregularity of the cutting edges the nose was depressed, and she had scars around the mouth Unfortunately she was suffering from acute tonsillitis and eczema, and died a few days later A report, from the hospital where she was treated when aged 2 years, gives the following information "Diagnosis congenital syphilis Has been a weakling since 5 weeks old She has a twin, other child healthy Has been wasting considerably Wassermann reaction positive This child had a congenital fistula from the perineum to the rectum just behind the vagina Antisyphilitic treatment given and patient discharged still having treatment Result relieved'

In order to decide whether the twins were monovular, certain physical characters must be compared

—	K A	V A
Height	5 ft 1 in	4 ft 7 in
Weight	6 st 1 lb	5 st 1 lb
Head length	180 mm	179 mm
Head breadth	140 mm	136 mm
Hair whorl	Clockwise right side	Clockwise right side
Eye colour	Iris has brown inner ring and peripheral white spots	Iris has brown inner ring and peripheral white spots
Blood group	A	A
Hair colour	Very light brown	Very light brown
Ability to taste phenylthiourea (0 005% solution)	Present	Present

Comparison of the fingerprints, right hand with right hand and left hand with left hand, shows eight correspondences of pattern, according to Stocks (1933) less than 1 per cent of ordinary sibs have six correspondences and none have seven

In view of these tests and a certain general similarity of appearance it is probable that these twins are monovular and of the same genetic constitution One can only explain the difference in syphilitic infection by assuming that environmental conditions in utero were more favourable to one twin than to the other The physical inferiority of the syphilitic twin is shown by her smaller size and her mental inferiority is marked even though the healthy sister is feeble minded Since the parents are of low mental grade, syphilis can only be reckoned as a part cause of mental defect in the affected twin, but it may have reduced the grade from feeble mindedness to idiocy

The work was carried out under the auspices of the Medical Research Council and the Darwin Trust

MICROGNATHIA IN THE NEW-BORN

BY C. PAGET LAPAGE M.D. Vict. Manch.
F.R.C.P. Lond.

PHYSICIAN TO THE ROYAL MANCHESTER CHILDREN'S HOSPITAL

MICROGNATHIA, once we recognise it, is an obvious deformity because the lower jaw is so small, but the condition is not always diagnosed. Its effects may be severe and babies suffering from it have great difficulty in respiration with attacks of blueness of mechanical origin due to the tongue falling back and obstructing the throat; the infant thus appears to swallow the tongue. The condition has been called glossoptosis and indeed one's first impulse is to tie the tongue forward, but this, though it may give immediate relief, is practically certain to result in broncho pneumonia.

CASE HISTORY

The *following* case under observation at St. Mary's Hospital, Manchester, is a good example of micrognathia:

A full time male baby aged 2 weeks, normal delivery, birth weight 6¾ lb., was admitted because he was unable to suck for mechanical reasons, though there was plenty of breast milk available. He had had frequent attacks of cyanosis with difficulty in breathing and was dusky between the attacks. The bowels were regular and the stools normal.

Micrognathia in an infant aged [illegible] weeks

Family history.—He was the twelfth child, five having died, the two before him at 10 and 9 weeks because the lungs never expanded. The parents are normal, the mother aged 40. The other six children are normal. There is no suggestion of an hereditary deformity, but there might be a common factor in pregnancies.

On admission he was fairly well nourished with a rather dusky skin. The mouth was hanging open as shown in the Figure. The lower jaw was decidedly small in relation to the rest of the face and thus the chin receded. There was no cleft palate. No abnormal sounds were found in the heart, the lungs, or the abdomen. A radiogram of the chest showed fair aeration of the lungs and some dark areas at the roots.

Treatment.—The baby had to be fed artificially, but even with a feeder it was difficult. He vomited several times each day and there were frequent attacks of cyanosis which were relieved by propping him up and administering oxygen. It was found that posture had a good deal of effect on feeding and that the nearer the child was to being on his face the easier he was to feed. A splint was made for him as suggested by Eley and Farber (1930). It was unsuccessful and in fact increased the distress, appearing to hold the jaw forward, and it was not easy to keep in place.

Progress.—After improving a little the infant became worse and died; the post mortem showed a hypertrophied and dilated heart, especially on the right side. There was a suggestion of a slightly patent ductus arteriosus. The lower jaw was small in proportion to the upper. There was no evidence of any continuous pharyngeal obstruction.

CAUSATION

In this anomaly the smallness of the lower jaw shows as a receding chin (see Figure). Possibly the horizontal part of the jaw is more affected than the ascending branch. The angle between the mandibular body and the ascending branch is decreased, but alters later on as the milk teeth are accommodated. Eley and Farber state that this anomaly of the jaw, like other anomalies of the jaw and ear, is associated with the first branchial arch and cleft, and the deformity is probably due to imperfect development or irregular rearrangement of the tissues composing these transitory structures. Keibel and Mall (1910) hold that there may be some inhibitory process. This seems reasonable and most authors agree that the anomaly is a simple arrest of development of the jaw (e.g. Lenstrup 1925).

Davis and Dunn (1933) say: "The lower jaw being formed and united in advance of the upper acts as a matrix on which the upper jaw is formed. Considering the position of the child in utero, where the weight of the entire fetal body may be readily thrown on the vertex, it is easy to conceive how pressure of the sternal region in contact with the mandible might force the forming jaws together. If this undue force occurred at a time when the lower jaw was united and the upper jaw ununited, it is easy to understand how pressure on the chin could *force the partly calcified lower jaw backward*, straighten the obtuse angle to almost a right angle and prevent the union of the horizontal plates, causing a cleft in the soft tissues of the palate without involvement of the alveolar ridge or lip. It would also account for the backward displacement and small size of the tongue."

According to Keibel and Mall—

> the mandible reaches its characteristic shape by the middle of the third month of fetal life. At this time the lips project about equally. Later the upper lip of the embryo grows more rapidly so that in the fourth and fifth months it projects markedly beyond the lower lip. Normally, by a greater growth of the lower jaw and lip, this difference is overcome. If, however, some inhibitory factor such as that mentioned occurred, the early fetal arrangement might be retained and deformity result."

This explanation seems the more reasonable in view of the fact that the jaw develops under treatment (Eley and Farber 1930).

The possibility of an hereditary element must not be forgotten and Pfaff (1913) showed the deformity to be hereditary in 50 instances and in some cases traced it through several generations. The family history in my case suggests that the last three children may have died from a similar cause and that there may have been some abnormality which developed in the mother as age advanced.

TREATMENT

Tying the tongue forward with sutures [illegible] is dangerous both from local considerations and from the possibility of broncho pneumonia. Splints failed in my case but have been used with success by Eley and Farber. Postural feeding, including feeding the child by lying on his face, may succeed with special care, but the jaw may not develop as fully as after other methods. This makes us realise that the first principle in treatment is to ensure development of the lower jaw. The lower [illegible] naturally reach out and up to [illegible] and [illegible] and Dunn (1933) to suggest another form of postural treatment. First of all the baby should be made to suck upwards. The mother should sit erect when breast feeding and not allow the weight of the breast to fall on to the child's chin. They also suggest an appliance fitted to the feeding bottle, which keeps the mouth a little distance from the teat and thus forces the child to reach out its lower jaw in the effort to suck. This helps the lower jaw to develop and counteracts the deformity naturally. Davis and Dunn show that it is quite probable that the jaw can be made to develop rapidly by mechanical treatments which aid nature. Furthermore, if no effort is made for further development of the lower jaw, adults may be condemned to hypoplasia of the lower jaw with vegetative changes in later life due to maldevelopment of the nasopharynx and imperfect ventilation. Robin (1934) shows that such work can be continued in later childhood.

The prognosis as regards both survival and development of the jaw is quite good in cases that have had suitable treatment, but there is probably a form of hereditary micrognathia running in families which is not amenable to treatment. The occasional cases, provided they have no associated congenital deformity and have developed no atelectasis, can recover with suitable exercises and management. It must be emphasised, however, that they need considerable care and individual attention before they are cured.

CONCLUSION

Micrognathia is not a common disease, but babies suffering from it may die and be labelled as inanition and congenital heart disease. They are not diagnosed and have no treatment. It is therefore worth while drawing attention to the condition, so that it may be recognised and effectively treated.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

AT a meeting of this section held on Jan 26th the chair was taken by Sir CHARLTON BRISCOE, the president, and a discussion on the course and management of

Congenital Heart Disease

was opened by Prof BRUCE PERRY. He said he thought the best classificatory basis was that of Maude Abbott into cyanotic and acyanotic groups. He would exclude gross malformations and those incompatible with life and unrecognisable clinically. In many cases the exact defects present could not be recognised, even with the aid of radiography. The acyanotic group could be divided into those with no abnormal communications and those with arteriovenous shunt. In the former group could be placed aortic stenosis, coarctation of the aorta, and pulmonary stenosis; in the latter, patent interventricular septum or ductus arteriosus. Late cyanosis might appear in pulmonary stenosis ("cyanose tardive")

In the truly acyanotic cases the malformation had little or no effect on the activities of the patients, though some of them seemed to be liable to sudden death. Their great danger was superimposed bacterial endocarditis. Some 20 per cent of Abbott's cases had suffered this complication. Patients needed no restriction, but every effort should be made to eliminate sources of infection. It was important that these children should live normal lives and not be allowed to develop a cardiac neurosis. Those who might have secondary cyanosis needed the same management and should lead full and unrestricted lives. The cyanotic type of case must be treated according to the depth of cyanosis and severity of symptoms. Those who showed cyanosis very soon after birth rarely survived more than five years; such cases were those of transposition of arterial trunks with patent ductus arteriosus and foramen ovale. If the cyanosis appeared at about the age of five the patient did not usually live much after puberty, but if the cyanosis were deferred to puberty, as in the Eisenmonger complex, life might be long. A moot point was whether cyanosis was incompatible with tuberculosis. Pulmonary infarction in a cyanotic case might be wrongly diagnosed as tuberculosis.

Among school children most cases seen were acyanotic and had a patent septum. Of 87 children attending his clinic all lived perfectly normal and symptomless school lives. Very occasionally complete heart block might complicate a patent septum. Some clinical and pathological data suggested that the foramen in the heart might be gradually obliterated by fibrosis. The hole would not increase in size with the growth of the heart, and the apparent obliteration might be due to this fact. Rheumatic heart disease was frequent among reported cases of patent foramen ovale, though it was difficult to see any direct connexion. The third type of case, which might be called pulmonary stenosis or possibly was sometimes due to patent ductus arteriosus, had a systolic thrill over the pulmonary area. Of 40 such children all lived normal lives, as did another 10 with aortic systolic thrill and murmur conducted up into the neck.

The prognosis in acyanotic cases was, therefore, good. Cases with cyanosis should lead restricted lives, but the prognosis and degree of restriction depended entirely on the severity of the cyanosis and other symptoms.

Dr TERENCE EAST said that diagnosis was usually fairly easy if the patient lived for a few months. Cyanosis depended on hindrance of access of blood to the lungs or on a shunt. Pulmonary atresia was the extreme example. In one case he had seen the blood reach the lungs through enlarged bronchial arteries, the patient having worked successfully as a dental mechanic. Two of his patients had died of pulmonary tuberculosis. Puberty was a critical time. In one case of patent septum the murmur had disappeared at the age of four, probably the smallest holes made the most noise. Patients with congenital heart block often had an open septum, though the nature of the connexion was obscure. He had never seen cyanose tardive. He had notes of 15 cases with pulmonary systolic murmur, enlarged pulmonary artery and loud, palpable closure of the pulmonary valves; all lived unrestricted lives and seemed healthy. Perhaps the lesion was a stenosis with dilated artery beyond it. Some of the cases of aortic stenosis with fused calcareous valves encountered in later life might have started as congenital abnormalities. Coarctation seemed to be well tolerated. All patients being liable to infection on their abnormality special care must be taken of them in all mild febrile attacks Pregnancy seemed safe with patent septum or ductus, provided the ventricle was good but a patient with cyanosis should not run the risk. If the condition was well tolerated acyanotic cases might be accepted for life assurance though the policy must be heavily loaded

Dr C **Muir** described a group of school children to which had been added some infants and adults In the very young diagnosis was difficult if not impossible. Full and unrestricted school life had given no evidence of strain on the heart in the maladie de Roget No case of heart block had been associated with patent septum. Two patients had gradually lost their physical signs. Extreme care of any possible sepsis was the only precaution taken In patent ductus there was some stress on the heart the aorta was hyperplastic and the pulmonary artery dilated though symptoms were uncommon. Each case must be judged on its merits One patient had severe anginal pain Subaortic stenosis had caused 4 deaths (2 from infective endocarditis)

Dr J W **Brown** spoke of cases he had seen at hospital 10 per cent. of them having cyanosis Intelligence seemed quite normal and it was a grave mistake to put these children in special schools If taught to read and write they could support themselves by sedentary work. Ideas of prognosis needed revision these cases might survive many years with a strikingly constant cyanosis Infectious diseases were surprisingly well tolerated but scarlet fever was dangerous Tuberculosis had occurred in several of the older members Nearly all the children were of normal height and weight One patient had become pregnant; labour had been induced in her first pregnancy but she had successfully gone through two subsequent ones. Patients were often disappointed at receiving no medicine but effective and friendly supervision was the important feature of management Oxygen was useless but bleeding was sometimes of temporary value

Dr A M **Gibson** asked whether the acyanotic group—*especially cases of coarctation*—should in adult life be *allowed* to take *part* in competitive athletics He related three cases In the first there was hypertrophy which seemed to indicate a burden on the heart The second had developed aortic stenosis on top of coarctation and had wished to become an air pilot The third was an old soldier with a to and fro murmur such as that heard in patent ductus arteriosus but without enlargement or disability He had lived a very hard life with no symptoms

Dr Evan **Bedford** said that school doctors in London were far too apt to refuse to allow children with congenital heart disease to attend school; this was a grave mistake Cases with dilated pulmonary trunk and pulmonary murmur and thrill were nearly all varieties of pulmonary stenosis and not of patent ductus arteriosus Dilatation was common beyond a simple stenosis The origin was probably a fœtal endocarditis of late appearance Patients with coarctation died either of intercurrent diseases some rupture or endocarditis strenuous effort should be forbidden them in adult life Patent interauricular septum gave no symptoms at birth and cases were not often diagnosed before the age of 20 A characteristic radiogram might be presented: tremendous dilatation of the pulmonary trunk aneurysmal pulmonary artery small aorta and enormous right ventricle enlargement Infarction of the lungs often followed In most cyanotic cases the heart was of normal size Auricular fibrillation and death with congestive heart failure was common but endocarditis was curiously uncommon in these cases of patent interauricular septum They showed cyanose tardive

Dr Leonard **Findlay** said that it was difficult in the acyanotic case to know whether congenital heart disease were present or not 40 to 50 per cent of children had a basal systolic murmur That murmur disappeared as the child got older and its cause was unknown it was to be regarded as functional unless it was due to patent foramen ovale He remembered one child of normal colour for a month who developed sudden cyanosis with a cough and died in a few days post mortem examination showed nothing but patent foramen ovale and extensive broncho pneumonia Presumably the congestion in the pulmonary circulation had caused mixing of the circulations This was probably the pathology of cyanose tardive

Dr Shirley **Smith** recalled an infancy syndrome similar to that described by Dr Findlay within a week or two the twin had also been admitted for the same syncopal syndrome and both had proved to have patent ductus arteriosus. Such cases belonged to the cyanose tardive group

Prof **Perry** in reply said he had never seen congenital heart disease with congestive failure or auricular fibrillation Coarctation was extremely difficult to diagnose and many patients lived active lives with very high blood pressure; nevertheless he would deprecate competitive games He would require a thrill as well as a murmur before diagnosing congenital heart disease

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this society on Jan 21st with Mr G C E **Simpson** the president in the chair a paper on

Congenital Cystic Disease of the Lungs

was read by Dr Alfred **Adams** He said that to explain the increase in the number of reported cases there was no evidence of a greater incidence but that it was more probable that improved radiological technique and interpretation and greater interest in chest surgery had led to better diagnosis He described two cases recently admitted to the Liverpool Sanatorium and diagnosed as suffering from congenital cystic disease of the lung One patient was a boy of 6 on whom a lobectomy was performed by Mr J T Morrison with eminently satisfactory results his records were available from birth Radiograms showed the condition of the lung at 3½ 5 and again at 6 immediately before operation and Dr Adams drew attention to the absence of progressive change that would be expected in infective conditions The other case was that of a man of 38 who had a collapsed or more probably accessory right lower lobe which showed well multiple cysts occupying the whole lobe the other lobes being normal. The speaker preferred to call the condition telangiectatic bronchiectasis He came to the following conclusions about the [illegible] it occurred more commonly than published reports suggested; it was due to intra uterine malformation infection or early extra uterine infection radiography was the best method for its detection but the gross macroscopic changes were greatly in excess of those suggested by the radiograms progress was slow and radiograms taken over long periods showed little advance, symptoms, where not caused by mechanical interference, were due to secondary infections of the cysts, and finally, he believed that surgery offered the best prospect of cure

Mr F RONALD EDWARDS, discussing the ætiology of congenital cystic disease of the lung, went further back than the extra uterine infection theory The most simple explanation of the condition, he said, was that it was purely congenital and due to lack of complete haustration of certain bronchi or bronchioles He compared it with the haustration which occurred during the development of other organs, such as the œsophagus, where the development might be incomplete, resulting in complete lack of opening, or, as one saw occasionally, cyst formation in the area that should have become the organ If in the lungs these cysts were isolated, the condition was one of congenital cystic disease, if, however, they communicated with bronchi, as they might if a further stage of development was presupposed, it became congenital bronchiectasis A further interesting clinical type was the non-tuberculous pulmonary abscess, which developed and on drainage did not clear up, section of the wall usually showed columnar or cubical epithelial cells, and those cases were usually ones of unsuspected congenital cysts of the lung in which suppuration had occurred, thus bringing their presence to light

Prostatectomy with Closure

Mr CHARLES WELLS had prepared a film illustrating Harris's technique of prostatectomy with immediate closure of the bladder In his absence through illness his paper introducing the film was read by the President

Mr Wells said that he had, so far as he knew, been the first in this country to record[1] a short series of cases operated upon by the Harris technique He had, in the meantime, been giving an extended trial to a different type of operation—suprapubic diathermy resection of the prostate—but in the past year had returned to the Harris operation He regretted that he had ever wavered in his loyalty to this operation, for he felt satisfied that of all the methods so far described it offered the patient the shortest and most comfortable convalescence with the smallest post-operative risk For the small fibrous type of gland he preferred McCarthy's transurethral technique, but there was also a small group of complicated cases in which special adaptations of the various means at one's disposal would be necessary Thus, in a small fibrous gland with a large diverticulum it was best to do an open operation and remove the diverticulum and then resect the prostate from above by diathermy He advocated spinal anæsthesia given in the lateral position and carefully controlled by adjusting the level of the spine by means of the kidney bridge In poor risks he favoured an underdose rather than an overdose and suggested that supplementary anæsthesia with gas oxygen should be given On the other hand, he thought that a full general anæsthetic without spinal was contraindicated, since the Harris technique prolonged the operation very considerably The film showed also bilateral vasoligation and by means of special lighting it had been possible to illustrate quite adequately all the steps by which the prostatic bed was repaired Mr Wells said he now liked to use a transverse incision, it was his practice to test the adequacy of the sutures in the bladder before closing the abdominal wall and he had recently reverted to draining the space of Retzius The series of cases upon which the paper was based comprised 30 operated upon by Harris's technique and 20 by McCarthy's in the period of eleven months immediately past

Mr A KIRK WILSON said that he noted in the film that the hæmostatic sutures in the rim of the prostatic cavity were cut short immediately they had been tied. He himself had found that oozing points between the sutures could be controlled if the ends were left long and tied together as described by Harris He favoured a rather longer incision that would allow the surgeon's hand to pass between the recti muscles and make enucleation possible without contaminating the left hand at the rectum The bimanual enucleation seemed to be a retrograde step from the Thomson Walker operation In his most recent cases he had discontinued complete closure of the bladder A small tube acted as a safety valve and in uncomplicated cases there was no contamination of the wound with urine, it could be removed on the fourth day and the average time of confinement to bed was not prolonged more than a few days

Dr W B BENNETT remarked that the subject was of special interest to those who had reached the "prostatic age," and that the improved technique and shorter convalescence would encourage any sufferer to submit to operation with less apprehension than in comparatively recent years

Mr COSBIE ROSS pointed out that many points of interest and importance had been raised. He considered that the secret of success in prostatic surgery lay in accurate selection For example, he quoted a recent personal series of 110 cases which were divided as follows —

Suprapubic prostatectomy	40
Transurethral resection	35
Suprapubic resection	4
Death before operation	6
Conservative measures	16
Refused operation	2
Prostatic enlargement associated with some more serious condition	7

He added that by conservative measures he meant the regulation of fluid intake and output, double micturition, controlled by occasional examination and estimation of the residual urine, and possibly in some cases the operation of Steinach II He disagreed with primary closure of the bladder at the time of the operation Harris himself in his several communications had stated that he regarded the retrigonisation of the prostatic cavity as the essential feature of his operation, although the primary closure has invariably been the focus of widespread interest He emphasised the dangers of the serious complication known as clot retention when a thick adherent clot spread over the base of the bladder, this might occur in spite of the most stringent post-operative precautions When it was necessary the same day or the day following the operation to reopen the bladder in order to remove this clot, the patient's chances were considerably lessened. He had the greatest admiration for the retrigonisation of the prostatic cavity advocated by Harris, and had practised this procedure himself, but considered that drainage with a water suction pump was a reliable and infinitely safer method of conducting the post-operative treatment Using this method, the abdominal wound was kept relatively dry until healing was far enough advanced for the fistula to be closed by strapping over the wound with Elastoplast He added that another objection to the primary closure of the bladder was the large size of the in dwelling catheter required, as this was an occasional cause of meatal stricture

REVIEWS AND NOTICES OF BOOKS

The Extra Pharmacopœia Martindale

Twenty first edition In two volumes Published by direction of the Council of the Pharmaceutical Society of Great Britain. London The Pharmaceutical Press 1936 Vol. I Pp 1182 27s 6d

THE Extra Pharmacopœia as produced by Martindale father and son was one of the few books which the medical practitioner the analyst, and the pharmacist cannot afford to be without The twentieth edition which appeared just before Mr W H Martindale s death embodied the experience of fifty years and even then he was not satisfied, for he wrote in the preface We plead heart and soul for more sportsmanship in our avocation The Pharmaceutical Society has taken over all that was good in the production and has had at its command the money and skill to revise and reset the whole book.

The editor of this coming of age edition is Mr C E Corfield whose experience as editor of the British Pharmaceutical Codex apart from that gained by many years of research qualified him to take over the heroic task. It is an achievement that in a book running to well over half a million words the editor has been able to include in the appropriate places a synopsis of the Addendum 1936 to the British Pharmacopœia 1932 Thus on page 378 in the monograph on cinchophenum is found B P Add. 5 to 10 grains (0 3 to 0 6 g.) B.P 32 gave max dose 15 grains —and this is not an isolated instance Note also the well-considered use of abbreviations although the full Latin names of substances—e g Carbonei Dioxidum—appear when they must The fuller use of Latin titles is a little unexpected—e g Hepas as the heading of liver extracts including stomach products We welcome the inclusion on page 910 of a reference to the effect on streptococcal infections of Prontosil and some of its derivatives given by mouth. No page has escaped revision but what is more remarkable is the amount of the original text which was considered worthy again to see the light in these more sophisticated days. Even the therapeutic index at the end has been taken over In fact we miss nothing except an unimportant table of infectious diseases. Some rearrangement has proved desirable. Instead of hormones and glandular products being grouped in one section entitled animal organotherapy they are now distributed in separate sections under the headings adrenaline œstrin and so forth Space has been saved by deleting notes on some of the older drugs The book carries still further than before the entry of synonyms and proprietary names the asterisk and registration numbers given in the old Martindale have now been replaced by the name of the manufacturer and/or agent and the town a system which has been tried out and proved in an appendix to the B.P C 1934

The materia medica alphabetically arranged occupy 922 pages and the section of vaccines, sera toxins and antitoxins accounts for 66 of the remainder The rest of the space is chiefly occupied by what is virtually a monograph on poisons and their relation to medical and pharmaceutical practice The arrangement is most convenient and the medical man who keeps the new Extra Pharmacopœia on his desk will rarely be caught out in his interpretation of the Poisons Rules

The Truth about Bright s Disease

By WILLIAM R OHLER, M.D Harvard University Cambridge Mass London Humphrey Milford Oxford University Press 1936 Pp 80 4s 6d

ASSUMING that the layman wants to know about Bright s disease it would be hard to find for him anything more suitable than the present item in the series called Harvard Health Talks Different aspects of the disease are outlined in simple non-technical language and if it is over-simplified in places allowance must be made for the complexity of the subject In the interests of accuracy however it should not be said (p 26) that casts are caused by damage to the glomerular tufts While in many instances their presence is associated with such damage there are conditions such as Bence-Jones proteinuria where the tufts are uninjured Many may pick up this book to learn what they can of prognosis hence it is deplorable that the bugbear of renal failure should be paraded in connexion with persistent idiopathic hypertension Uncomplicated simple ischæmic nephritis does not entail renal failure Though it can hardly be recommended as a bedside book for the nephritic, it might be read with profit by those who have the care of children They might as a result more often summon the family doctor when infections are complicated by symptoms suggestive of acute nephritis It cannot be doubted that many of the milder attacks of nephritis in children pass unheeded only to lay up trouble for the future and of no disease is it truer than of Bright s disease that in early treatment lies our only hope

Disability Evaluation

Principles of Treatment of Compensable Injuries By EARL D MCBRIDE B S M.D F.A.C S Assistant Professor in Orthopedic Surgery University of Oklahoma School of Medicine &c Philadelphia J B Lippincott Company 1936 Pp 623 38s

IN this country the Workmen s Compensation Acts provide for the payment of compensation to a workman so long as he is incapacitated from earning by reason of an injury sustained at work. The amount of his compensation is calculated upon his loss of earnings, not upon his anatomical imperfections Similar Acts in the United States of America base the payment of compensation on the anatomical or physiological defects resulting from injury its amount being related to pre accident earnings In Oklahoma where the author practises loss of the entire arm is compensated at 250 weeks payment loss of the hand at 200 weeks Partial loss of the hand would be assessed at some percentage of 200 week Dr McBride s aim has been to resolve all injuries into terms of percentage loss to the limb or to the whole body—to determine as he puts it in the preface the extent of personal incapacity estimated with arithmetical preciseness

On p 47 is given the key to his method. He takes the normal part and divides full working capacity into the following percentage factors quickness 10; coördination 20 strength, 20 security 10; endurance 20 safety 10 and physique 10 Functional incapacity is estimated by factors with percentage values as follows; slowa tion 10 awkwardness 20 weakness 20 insecurity 10 fatigue

20, increased risk, 10, and impaired prestige, 10 He does not expect everyone to agree with him in his allocation to the various factors, someone may wish for instance, to increase the value of weakness in functional incapacity to 40 per cent, but if this is done other factors must be decreased accordingly Working with this key, tables are given in which an attempt is made to estimate the percentage of incapacity in almost every type and condition of injury Taking at random a few examples—total ankylosis of the wrist in 70° dorsiflexion is equivalent to 27 6 per cent total loss of the arm, ankylosis of the thumb at the carpo metacarpal joint in abduction equals 26 5 per cent loss of the thumb, ankylosis of the elbow in full extension equals 56 per cent loss of the arm Tables are given of the period of incapacity likely to result from any particular injury On p 541 we are told that the average period that will elapse before a man should return to work after complete division of the median nerve "treated by operation over three months" after the accident is 64 weeks, sciatic nerve, 64 weeks, musculo spiral, ulnar, and peroneal nerves, 52 weeks These figures are given as the "approximate normal healing period in peripheral nerve paralysis" No attempt is made to differentiate between types of work so that complete recovery both of epicritic and protopathic sensation as well as of muscular power must be assumed at the end of the period stated On p 237 we are told that complete dislocation of the knee joint requires eight weeks' surgical care, twelve weeks' observation, and is able to begin work in 36 weeks, and on p 128, that destruction of the shoulder joint with suppuration has an average period of surgical care of 16 weeks and is able to begin work in 52 weeks

The idea of this book is well conceived Unfortunately injuries to the human body cannot be "evaluated" by abstruse mathematical calculations in a study Only by long experience of actual examination and by the careful follow up of large numbers of cases—not only until they cease treatment but until they have remained at work for a period of months—can any accurate estimate be obtained of the disability that may result from certain injuries in certain types of work. The danger of this kind of book is that it may be bought and quoted by medico legal experts in court We hope that the American courts will take a more generous view of the workman's injuries than does the author

---

The British Journal of Surgery

The January issue (Vol 24, No 95) contains the following articles —

ROTATION AT THE SHOULDER A CRITICAL INQUIRY By Leo McGregor (Johannesburg) Arguments are advanced to show that full abduction of the humero scapular joint involves full external rotation and similarly that full flexion is possible only with full internal rotation The author proposes that it is not essential in treating recent injuries of the shoulder joint to restore the full range of abduction and he advocates a position midway between full abduction and full flexion as being both comfortable and convenient

MALLET FINGER By I S Smillie (Edinburgh) Satisfactory results were obtained in 35 patients who were treated by the method here described for rupture of the extensor tendon at its insertion into the base of the terminal phalanx A tube of Cellona plaster bandage is applied around the finger It dries whilst the patient holds and presses the joints in the required position of flexion of the proximal interphalangeal joint and hyperextension of the terminal joint

BLOOD PRESSURE DURING SPINAL ANÆSTHESIA By E Falkner Hill (Manchester) A pronounced fall of blood pressure has been observed in acute abdominal cases occurring spontaneously with the relief of pain This is regarded as primarily due to abolition of pressor impulses by the spinal anæsthetic and, except in cases of severe dehydration, calls for no special treatment

A COMPARISON OF THE RESULTS OF SPINAL FIXATION OPERATIONS AND NON OPERATIVE TREATMENT IN POTT'S DISEASE IN ADULTS By G K McKee (Norwich) In investigating 150 patients over sixteen the conclusion was reached that fixation by bone graft is contra indicated in the active stage of Pott s disease, since it delays anterior fusion of the bodies without providing sufficient posterior fixation to stabilise the vertebral column It gives good results in late cases of fibrous union, where anterior consolidation has progressed as far as possible

GASTROSCOPY ITS HISTORY, TECHNIQUE AND CLINICAL VALUE, WITH REPORT ON SIXTY CASES By Hermon Taylor (London) The instrument used is a flexible gastroscope, capable of transmitting an image despite a moderate degree of curvature of the tube, and its use is described as painless, safe, and reliable The value of the method in the diagnosis of gastritis, ulcer, and cancer is fully illustrated in the reports

FUNNEL NECK DEFORMITY OF THE BLADDER By J B Macalpine and D S Wilson (Salford) The deformity is considered to be due to weakness of the internal sphincter at the base of the bladder It occurs typically in syphilis of the central nervous system, but is found also apart from nervous disease It is demonstrated by cystoscopy but rarely by cystography

THE ASSOCIATION OF INGUINAL HERNIA WITH TRAUMATIC PERFORATION OF THE INTESTINE By Ian Aird (Edinburgh) Four cases are reported in which rupture of the intestine and peritonitis followed acutely on an abdominal injury The mechanism suggested is a traumatic force acting on a loop of intestine fixed at the ileocæcal or duodenojejunal junction and gripped at the other by contraction of muscles at the hernial orifice

CHRONIC PEPTIC ULCER OF THE ŒSOPHAGUS A REPORT OF EIGHT CASES By Alexander Lyall (Glasgow) The ulcers were incidental findings during post mortem examinations There were two main types, one shallow and extensive, the other smaller but deeper and associated with heterotopic gastric mucosa

RENAL RICKETS By N L Price and T B Davie (Bristol) The condition is defined as "a disease of childhood characterised by skeletal demineralisation with resultant deformity and associated with chronic renal disease, which in uncomplicated cases terminates in uræmia" The relationship to hyperparathyroidism is discussed The case described is regarded as being primarily of endocrine rather than of renal origin

CHOLESTEROSIS OF THE GALL BLADDER A REVIEW SUPPLEMENTED BY PERSONAL OBSERVATION OF 87 CASES By W Arthur Mackey (Glasgow) The view is taken that "strawberry gall bladder' is not a specific lesion and is not necessarily associated with inflammation Symptoms when present are due to coincident gall stones, which occur in one third of cases or are functional in origin and are unrelated to the lipoid infiltration of the mucosa Cholesterosis does not demand removal of the gall bladder

TOXIN FORMATION IN BURNED TISSUES By W C Wilson, J S Jeffrey A N Roxburgh, and C P Stewart (Edinburgh) The toxic nature of œdema fluid formed in burned tissue is demonstrated by experiments on rabbits and mice The toxicity is absent at 4 hours and maximal at 48 hours it affects the nervous system the circulation and the central cells of the liver lobules The toxin appears to be associated mainly with the globulin fraction

A visit of the Moynihan Surgical Club to Prof Grey Turner at the British Postgraduate Medical School is described and there are also brief descriptions of several cases of special interest

THE LANCET

LONDON SATURDAY FEBRUARY 6 1937

RENAL TUBERCULOSIS

Modern methods of clinical examination such as cystoscopy and pyelography have added much to the precision of diagnosis in tuberculosis of the kidney and the recognition of the early case is altering our conception of the disease In other organs too notably the lung tuberculosis is being diagnosed earlier with the result that renal tubercle has fallen into its right place as part of the picture of a chronic infective disease in which there is metastasis in the kidney often accompanied by metastases elsewhere A few weeks ago Mr Hugh Lett in the Bradshaw lecture gave an illuminating account [1] of tuberculosis of the kidney in this modern setting He quoted figures to show that in the cases coming to nephrectomy there was evidence or a history of tuberculous disease elsewhere in 84 per cent The experience of other writers tends in the same direction In our present issue Dr M C Wilkinson reports cases of genito urinary tuberculosis at Black Notley Sanatorium of which 62 per cent had lesions elsewhere the largest number being in the skeletal system On the other hand Mr Frank Harvey s figures on another page show only 17 per cent of cases with lesions elsewhere the majority of them again being in the bones The prevalence of pulmonary lesions is not much less—a point brought out in Dr Wilkinson s figures There is therefore fairly good evidence now for believing that tuberculosis of the kidney is in the main a metastatic lesion the emphasis has consequently *shifted from* the local to the general care of a tuberculous person

Another point brought out both by Mr Lett and Dr Wilkinson is the greater prevalence of the disease in adults In a recent study [2] however Dr C P Mathé of San Francisco has found 10 per cent of his 4698 cases of unilateral renal tuberculosis in the second decade of life and he relates recovery after nephrectomy in two children a girl of 8 and a boy of 10 Dr Wilkinson suggests that the lymphatic system is a better barrier against the generalisation of the infection in childhood than it is later in life There are probably other factors Chronic tuberculosis is a disease of adult life its pathological picture is different from that seen in children and the renal lesion is a prominent part of the adult infection These facts have a bearing on the question of operative treatment In Mr Lett s opinion nephrectomy is not an operation of urgency for renal tuberculosis Early cases and those in which the symptoms are acute should undergo general treatment first all the writers mentioned insist upon the value of sanatorium treatment which is as necessary before as after operation Treatment of the tuberculous kidney is in fact following in the wake of treatment of the tuberculous joint operation if it is performed is to be regarded as an unwelcome necessity With all the progress that has been made the prognosis of renal tubercle is still grave Recovery from unilateral disease after operation is placed by Mr Lett at 55 to 60 *per cent* for the hospital class of case and 80 per cent for the well to-do In bilateral disease the outlook is grim but Dr Wilkinson s figures show rather unexpectedly, that in the sanatorium even the association of genital with renal tuberculosis does not appear to increase the gravity of the disease Many of these points were emphasised at a recent meeting of the section of surgery of the Royal Academy of Medicine in Ireland Early diagnosis and sanatorium treatment are the things to aim at Operative treatment should only be undertaken after a careful survey of all the facts and with the full realisation that renal tuberculosis is part of a general infection

PENNY-IN THE-SLOT PATHOLOGY

Under the title the Pathological Yardstick Dr L G Cole of New York has written [1] on the diagnosis of malignant gastric lesions Out of 51 specimens of stomachs examined microscopically between 1927 and 1932 he chose 8 they did not represent straightforward cases but he claims that 8 out of 51 routine examples cannot all be rarities Sections from these specimens were shown or sent to a score or so of eminent American and Canadian pathologists who were asked to make diagnoses and give the grounds on which they were based The divergences of opinion are remarkable and taken along with Dr Cole s accounts of the patients histories and of his own radiological findings they make amusing reading In Case II 23 out of 24 pathologists diagnosed a malignant condition some carcinoma some sarcoma or lymphosarcoma only one regarded the lesion as a chronic inflammatory one and he seemed to be justified in Dr Cole s view because the patient was alive and well 12 years after her partial gastrectomy In other cases the pathologists were more nearly equally divided in their decisions for or against malignancy Dr Cole seems to have been so distressed at their lack of unanimity that he has undertaken the study of microscopic sections himself and promises us shortly another article in which he will describe 25 points of differentiation of new growing tissue from inflammatory lesion 25 points moreover of which not a single one was recorded in the reports of the criteria of his 24 pathologists

This threatened invasion of its territory may rouse a little apprehension in the pathological world but at the same time it gives the pathologists an opportunity to protest against a common misconception of their function Dr Cole seems to regard them as penny in the slot machines drop in a slide pull the handle —and why are the reports not all identical? The morbid anatomist function is to study the structural changes in the tissues of diseased animals, including man When he brings that study to the service of patients, he is entitled to see the whole of a surgical specimen, to direct the cutting and staining of sections himself, and, if he wishes, to know the patient's history, perhaps he should exercise that right more fully than he often does He is also entitled to disclaim omniscience, there is much in morbid anatomy that he does not yet understand—otherwise it would not attract good men to its study—and the clinician has no business to demand a yes or no answer even to such an important question as the presence of malignancy Honest doubt, with the reasons for it, is a better contribution to pathology, and in the long run to the management of patients, than cocksure dogmatism with a dash of guesswork in it The final responsibility in diagnosis and treatment rests always with the physician and the surgeon Laboratory help nowadays is so extraordinarily valuable that the temptation to rely on it blindly is very strong Yielding to that temptation leads to two evils mistakes, from which the patient suffers, and a degenerative process among the laboratory workers themselves, who, in seeking to meet the demands so made on them, neglect the intelligent study of their subjects and convert themselves into automatic machines

---

[1] *Surg Gynec Obstet* [illegible] 193 p 6 7

It is just this problem which has provoked Dr DYKE's presidential address to the Association of Clinical Pathologists, which we print on another page The clinical pathologist is the pathologist whose interest lies chiefly in the service pathology renders to medicine Since medicine has always as its prime task the day to day care of patients — diagnosis, prognosis, and treatment — these matters make also a first claim upon the clinical pathologist's activities Dr Dyke argues that, to meet that claim, the clinical pathologist must not only be a master of his own extensive laboratory techniques but also be something of a physician himself He must have had a good training—and preferably a higher qualification as evidence of it—in clinical medicine, and he must remain always in the closest touch with physicians and their work in the wards Such cooperation is certainly essential if the physician is to make the fullest and, at the same time, least wasteful use of the laboratory, and if the laboratory-trained worker's precision of thought is to have its proper influence on the medical mind Dr Dyke's ideal head of a pathological department is to be trained in this way, he is to be a technically expert morbid anatomist, biochemist, bacteriologist, and hæmatologist It is a large order, and it leaves no room for contact with non clinical pathology in any of its branches, or for any excursion into experimental medicine For the smaller hospital, however, there is no good alternative, its pathological departments must be first and chiefly "clinical" In the large university or teaching hospital, on the other hand, we feel that the pathological department has a wider function—the study of pathology in all its aspects, with the advancement of knowledge as its supreme aim The hospital naturally provides much material for this study, but is not its only source, the department in return renders service to the hospital and for this purpose must have among its staff many members whose training and outlook towards medicine are what Dr Dyke describes, though they will more often confine themselves perhaps to one branch or another of pathology, not each trying to be competent in the whole technical field So the pattern of development may vary in different parts of the medico scientific organism, which has to evolve a long way yet, with much differentiation and integration of structure and function The clinical pathologist is a cell which may at present be a little difficult to assign to one germinal layer or another, but there is no question of his increasing value and importance The essential thing is that he shall not lose his nucleus

THE RUSSIAN TRIALS

THE two State trials in Moscow have shocked those of us reared in the tradition that the first duty of a court of justice is to ascertain facts, and that none should be adjudged guilty except on unshakable evidence There has been speculation about the methods used to evoke, from revolutionaries so tough, confessions so abject and so damning Can they be the result of torture, mental or physical, do the Soviet police use drugs, or hypnosis, to break down resistance or implant falsehoods, can the strange behaviour of the accused be explained by their unstable temperament, or is the whole affair a hoax staged by a dictator for his own purposes? The suggestion that drugs are used is nowadays not as wild as it might have seemed a few years ago It is recognised that injections of barbiturates such as *Evipan, Nembutal, and Avertin produce in suitable dosage a dreamy state of mind in which a patient may lose his inhibitions and talk more* freely about his past experiences Partial narcosis of *this kind is sometimes employed in mental* therapy when the object is to get information that will throw light on the patient's neurotic trouble The rôle of the drug is to increase the rapport between patient and physician, but it does not open the unconscious mind as one lifts the lid of a box, and the work of interpreting what the patient says is made difficult because facts and fantasies come forth all mixed up as they appear in dreams—in other words, they offer clues, not evidence Drugs, furthermore, do not permanently change the attitude of mind towards persons or things, though they may favour tendencies to change of outlook or attitude In the patient's mind there is always a picture of the person giving the drug with good or evil intention according as the patient is guided by his unconscious fantasies

The drug hypothesis alone does not explain the apparent volte face in these Russians, but there may have been a combination of drug and hypnotism The word hypnotism is used in different senses, and if one regards it as the overpowering of the subject's will by the superior "force" of the hypnotist, one would not expect it to be very successful in changing some of the most vigorous and masterful minds in Europe Another and wider view of hypnotism however connects it with the impulse of submission The patient identifies the hypnotist with his own conscience and at least for a time accepts his standards and commands as if they emanated from himself On this view hypnotism is an example of the process of accepting another attitude of mind towards people and events—a process which is most active in infancy and adolescence and which accounts for the phenomena of religious conversion and for sudden changes in people of unstable temperament The mental impulses responsible for hypnotism are closely linked with those that bring about the submission of the group to a leader men will unwittingly (by a process of idealisation) set up their political leader or dictator in the position of a mental ruler or law giver in their own minds The readiness to submission can be traced to the attitude of emotional submission which the infant experiences towards its parents and which later by substitution is displaced on to the community in the form of submission to social conscience

This was no common trial of common prisoners two rival attitudes towards revolution are represented. **STALIN** stands for a concentration of energy upon an improvement of the conditions in the U S S R aggressive impulses being directed in the main upon inanimate nature—harnessing rivers conquering the Arctic and so forth Some of the old guard of the Revolution on the other hand wish to see the immense force of the aggressive impulse in the Russian people turned to world revolution—a world revolution that must begin moreover by overturning at whatever cost the present conservative rulers of the Russian State From a psychological standpoint the issue depends on the decision where to turn aggression. Of course aggression cannot be turned like a turret gun now here now there but one policy can give expression to fantasies and impulses that see revolution rising in every quarter of the world another can express the desire to get satisfaction from beating the Western nations at their own game of mechanised production from grandiose schemes of record breaking canal-digging and so forth Above all the revolutionary must be successful He employs the dangerous weapon of aggressive revolt (in contrast to the inturned or passive revolt of the Ghandi type) and the excitement it rouses makes for instability and the overaction of feelings of guilt His constructive impulses (contrary to what is usually supposed) are often very strong and to the social psychologist the revolutionary differs from the reformer chiefly in the reactions of guilt arising when an attempt is made to change the old order If he fails his mental peace is endangered not merely by the thought of toil wasted and hopes destroyed but by a burden of unsublimated hate that finds no outlet To all this we must here add the ingredient of self revelation and self torture dear to the Russian heart the pangs of conscience which are the warp and weft of Russian novels and now appear in the repentances of lazy comrades in the factory wall newspapers lend power to the central government both by reinforcing submissiveness and by giving colour to its puritan politics The kind of State trial we have been witnessing was not a foreign thing to the accused it is nowadays found wherever the concept of a Perfect Ruler is thought to be a necessity Under the old régime in Russia the trial of the Jews for ritual murder of a Christian boy was a method of diverting hatred from the Czar and Church the Jews again are scapegoats in Germany to-day for a similar reason and the men now executed themselves belonged to a party that sees everything as pure Red or pure White The analogy that has been drawn for English readers that the indictment is as fantastic as if **LLOYD GEORGE** bargained with Germany for an invasion of England by promising that **HITLER** should have Yorkshire is quite beside the mark. Politics in England are not a matter of perfect Kings and Premiers and wicked Opposition but of compromise between people not wholly right or wrong We in England find the trial and the confessions incredible because we cannot credit sane men with extremist views and passionate remorse But the Russians (under old or new régime) run to both

MEDICAL HONOURS

THE highest honour for a practising medical man in this year's list (see page 352) is the K C V O. which goes to Mr John Fraser regius professor of clinical surgery in the University of Edinburgh. Four of the 20 knights bachelor are doctors Medical research receives recognition in the persons of Prof J C G Ledingham F R S and Dr J A Arkwright F R S It is fitting that these two eminent collaborators at the Lister Institute who worked together in earlier days and have since developed different branches of bacteriology should be knighted at the same time Prof Ledingham has of late years been concerned with the study of viruses notably that of vaccinia and more recently of the Rous tumours and Dr Arkwright by his work on foot and mouth disease and tuberculosis has linked the activities of the Medical Research Council and the newer Agricultural Research Council of which he is an active member Dr E K Le Fleming a practitioner member of the General Medical Council guided the deliberations of the Representative Body of the British Medical Association with conspicuous success and is now the esteemed chairman of the council of the Association Dr Morris-Jones who practised in Colwyn Bay for twenty years and is consulting honorary physician to the West Denbighshire Hospital, is honoured for his political services culminating in his work as Junior Lord of the Treasury Major General T S Coates deputy director of medical services Aldershot Command receives the C B and so does Major General A W M Harvey who holds a corresponding post in the Northern Command India Dr W H Kauntze director of medical services Uganda Protectorate receives the C M G Of these honours left for a fourth associated with medicine special mention is due to the efforts of Lady Williams who is made D B E to secure more comfort and safety in childbirth for British mothers

ANNOTATIONS

EARLY CANCER AND RADIOTHERAPY

In common belief cancer is still an incurable disease It is because of this belief that the use of the word is avoided, and it is the reason for much of the delay in seeking advice The patient who suspects the presence of "cancer" is apt to assume that if his fears are correct nothing more can be done, and even the practitioner is tempted to try some mild form of treatment before sending a patient to a cancer therapy centre because of the alarm aroused when he makes the suggestion The Christie Hospital and Holt Radium Institute have wisely made use of their annual report[1] to emphasise the curability of early cancer They deal in particular with X ray and radium therapy, although they remind us that in certain sites surgery remains pre eminent It is claimed that this survey covers practically the whole range of common cancers, except those of the digestive system In 1933 1013 cases of cancer were treated, and of those 536 were alive three years later—53 per cent The figure includes all the cases treated, the early with the late, and the importance of the stage of the cancer is brought out by the figures for cancer of the mouth Of the cases treated in 1929, 15 were early and 60 per cent survived five years, of the remaining 137 more advanced cases 20 per cent survived five years, none of the very advanced lived even for three years The figures for cancer of the breast, womb, skin, &c, are similar, and the report goes on to say that the results depend not only on the disease but on the possibility of obtaining correct treatment at an early stage

This is the crux, for in the long run the cancer patient will come to the place at which he receives speedy and effective relief Arrangements for this purpose in Manchester are excellent, including, as they do, a regional scheme for radium treatment on which we recently commented in a leading article[2] The Manchester Institute is happy in having secured Prof J S B Stopford as its vice chairman and in having a committee of management anxious to develop the hospital and its services It is not only the extension of services to patients living at a distance, but new building and plant, including four additional X ray outfits, will soon be available and will make the department one of the largest and most modern X ray units in the Empire A collateral expansion is going on at the same time in the physics department The scheme tacitly recognises the fact that radiotherapy is both expensive and difficult, it is only with a highly trained and skilled staff and adequate team work that the dangers can be eliminated Institutes like this with their large numbers of cancers of various regions—227 cases of cancer of the mouth and 161 of the womb were treated during the year—can do good not only by curing their quota of patients but by the clinical research which determines the best measures and procedures, so that in time it is possible to deal safely and efficiently with certain types Such centres too provide the special training in radiotherapy required for the national centres, almost all of which now include X rays with radium for the treatment of cancer The supply of radiotherapists is still very limited, it is a small specialty which is growing daily in importance Only a centre with long experience and a permanent radiological staff can supply the teaching and clinical material.

---

[1] Report for the year ending Sept 30th 1936 From the secretary of the Institute, Wilmslow road Withington Manchester

[2] *Lancet* 1936 2 1277

HEALTH OF THE ROYAL AIR FORCE

Reports on the health of highly selected groups of persons must always provide some points of interest and although the Royal Air Force has not yet come of age, so that the more recent reports on the state of its health cannot as yet be contrasted so sharply and compared so favourably with previous reports as can those of the older services, the report[1] for 1935 makes tolerably cheerful reading It is satisfactory, for example, to learn from the report that the incidence of sickness shows a decrease of 6 per 1000 of strength, for cases admitted to hospitals and sick quarters, below that for 1934, and is the lowest figure so far recorded. Similar low records are noted in the incidence of venereal disease, the figure for which has fallen from 9 9 to 9 5 per 1000, and in the number of invalidings from the service which fell from 5 1 per 1000 in 1934 to 4 8 in 1935 Still more strikingly satisfactory is the decrease in the incidence of injuries and diseases among apprentices which has been halved, the figure per 1000 of personnel having fallen from 115 2 to 57 3 With so much on the credit side, it would be too much to expect to find nothing on the debit side of the account and the most regrettable feature of the report is an increase in the death rate to 4 8 per 1000, but when comparing this with the previous figures of 3 8 for the period 1928–34 and 4 3 for 1921–27, it should be borne in mind that the Quetta earthquake was responsible for 52 deaths, a contingency against which the medical services could not provide and which, it is earnestly hoped, is unlikely to arise again in the near future Far less tragic but perhaps, in a sense, more disquieting, is the marked increase of upper respiratory tract infections among apprentices, the incidence of which almost doubled itself, rising from 267 9 per 1000 in 1934 to 514 2 in 1935, suggesting possibly a lowering of resistance due perhaps to inadequate ventilation, or massive droplet infection occurring in shops or sleeping quarters or some such remediable factor It is, however, only fair to state that energetic measures to prevent such infection have already been taken at Halton which was the scene of two epidemics

The report is full of statistical data and contains many easily comprehensible charts and tables An interesting table of medical causes of rejection for flying duties shows that defective vision was by far the commonest single cause, rejections for this being almost equal to the total number rejected on general medical and surgical grounds The main causes of final invaliding from the service were first diseases of nervous origin which include mental disorder, epilepsy, and the psychoneuroses This group accounted for 46 invalidings out of a total of 118 Other major causes were tuberculosis (26 cases), ear and nose conditions (14), injuries (12), acute rheumatism and urinary disease (11 each), and diseases and deformities of the limbs (10 cases) Among the principal medical causes of temporary non effectiveness were first, injuries, secondly, gonorrhœa, and thirdly, upper respiratory tract infections with tonsillitis a bad fourth and influenza curiously enough among the also ran. Of the four geographical areas in which the R.A.F. operates the United Kingdom appears to be the most healthy Iraq the least, with the Mediterranean Littoral and India between the two. The incidence of venereal disease however though greatest in Iraq is lower in India than in the United Kingdom. The report shows that there has been a gratifying decrease in the incidence of many diseases abroad as well as at home notably in such conditions as dysentery malaria and phlebotomus fever. An increase in the number of cases of psychoneurosis occurring abroad is attributed in part at least to the Quetta earthquake and this catastrophe also accounted for a slight increase in the incidence of injury. An appended summary of the laboratory work carried out both at home and abroad shows a total of 54 885 special investigations done. Over 16 000 chemical or bacteriological investigations of urine were undertaken nearly 10 000 throat and nose swabs examined and 4051 samples of water were analysed mostly in Iraq. Many other investigations such as blood counts and examinations of blood for malaria, Wassermann reactions bacteriological examinations of pus and fæces, and microscopic examinations of skin scrapings and hairs from fungi were also carried out on a large scale.

---

[1] Air Ministry Publication 875 (1935) H M Stationery Office Pp 101 2s

At the hands of R.A.F. dental officers the personnel in the United Kingdom Mediterranean Littoral and Iraq received much dental treatment, and 9830 were rendered dentally fit during the year. Another 981 were brought to the same happy state by army dental officers in India Palestine Transjordan and Sudan.

ROYAL NATIONAL HOSPITAL FOR RHEUMATIC DISEASES

THE Royal Mineral Water Hospital at Bath dates back to Roman times and the modern foundation is based upon an Elizabethan Act which established the hospital for the poor from all parts of the country to benefit from the springs. For a time the Act was interpreted to mean that the inhabitants of Bath could not receive treatment at the hospital and even at the present day only 2 per cent of the patients are drawn from the city. As 25 per cent. of the patients have their homes in the London postal district there was justification for launching an appeal last week in London for the rebuilding of the hospital now renamed the Royal National Hospital for Rheumatic Diseases at a cost of £200 000. Sir Edward Grigg who presided at the meeting held by courtesy of the Vintners Company at the Vintners Hall in Upper Thames-street told of the arrangement by which the Bath city council had provided a site nearly four times as large as the present one and nearer to the springs. Two of the governors Mr Sidney Robinson and his daughter Mrs Prince had offered to contribute £50 000 provided that the foundation was laid within twelve months. Accommodation would be provided for 250 patients nearly 100 more than in the present hospital. Sir William Willcox speaking as vice chairman of the Empire Rheumatism Council welcomed the extension of the hospital as a greater opportunity for research into rheumatic diseases. Lady Snowden following Sir Francis Younghusband who spoke as a resident of Bath seventy years ago directed attention to the economic loss due to rheumatism. The cost to national health insurance is, she said £5 000 000 a year loss of wages amounts to four times that sum the equivalent of 6 000 000 weeks of work. The president of the hospital Mr C. G Mackay in thanking the speakers explained that funds were available to maintain the hospital, even with the additional beds their concern was to raise the money for a building which would benefit patients from all parts of Great Britain.

BLOOD CHANGES IN ECLAMPSIA

A FEW writers on eclampsia manage to keep their feet firmly planted on the ground of established fact but the temptation to rise on the waxen wings of fancy has made many share the fate of Icarus. Papers based on information rather than speculation are accordingly as welcome as they are uncommon and two recent examples deserve some attention. In the first Dr W J Dieckmann[1] reports the results of a large number of measurements of the hæmoglobin cell volume, and serum protein content of the blood in toxæmic and normal pregnancy. In eclampsia he finds that all three are generally raised sometimes relatively—that is compared with figures obtained at the same stage of normal pregnancy but often considerably beyond the normal limits in non pregnant women. The most obvious explanation of such increases is that water has escaped from the blood into the tissue spaces, and by direct measurements of total blood and plasma volume Dieckmann has shown that this is so. The lowered blood volume is most conspicuous when the convulsions coma and visual symptoms are most intense and it disappears as the clinical condition improves. In three fatal cases the blood remained concentrated in spite of intravenous injections of fluid.

It is evident from Dieckmann's paper that anhydræmia is not the cause of the eclamptic crisis but a secondary phenomenon. A clue to its probable cause is provided by the earlier work of G Haselhorst and K Mylius[2] concerning retinal changes in eclampsia. According to these authors the retinal vessels can be seen in a state of focal spasm, which is later overshadowed by exudate from the vessels. It is well known that vasoconstriction tends to increase the permeability of the vascular endothelium and there are good grounds for the suspicion that vasoconstriction is not confined to the retinal arteries in eclampsia. The presence of anhydræmia is accordingly consistent with what may be termed the pressor hypothesis of eclampsia but the cause of the vasoconstriction remains as obscure as ever. Dieckmann's observations also revive the question whether in spite of the œdema, intravenous injection of fluid may not after all be indicated in eclampsia. This question can be settled only by clinical trial but it seems doubtful that the fluids ordinarily used will remain in a leaky vascular channel long enough to lend material help to the patient.

In the second paper Dr J M Boyd[3] describes studies of the lipoid content of the plasma and red corpuscles in 40 cases of pre-eclampsia. He has been chiefly concerned with the phospholipoids (lecithin &c) and total cholesterol. The ratio of the former to the latter is apparently normal in some cases and abnormally high in others. Since the ratio is also high in eclampsia he suggests that the latter group of patients may be nearer the eclamptic state than the former. It is possible that the ratio may be useful in gauging the prognosis in pre-eclampsia, but the accurate estimation of blood lipoid is by no means simple and it is not certain that the clinical examination would not give equally reliable information Beyond this there is little to be said Not much is known about the significance of blood cholesterol in health, let alone disease, and still less about that of the phospholipoids An empirical quotient derived from two such mysterious entities could therefore hardly be expected to throw any light on the nature of eclampsia

EXPERIMENTS WITH A MICROVISCOSIMETER

SINCE the viscosity of plasma depends mainly on its protein content, the determination of the plasma viscosity should be a rapid and convenient alternative to the estimation of the plasma proteins Unfortunately methods for the estimation of the plasma viscosity have suffered from two disadvantages, one being their relative inaccuracy and the other that a fairly large volume of fluid is required T Satô (*Nagoya J med Sci* November 1936, p 187) describes an accurate method requiring only 0 2 c cm of fluid, using a simple viscosimeter of his own design He shows that with this method contamination with hæmoglobin does not cause a noticeable inaccuracy until the serum appears intensely red He finds that the serum viscosity of Japanese subjects, while varying widely in different individuals, tends to decrease with age, and that in similar age groups it is higher in males than in females Serum dilution brought about in various ways—e g, by bleeding and allowing the physiological restoration of the blood volume to take place, by replacing lost blood with Ringer's solution, and, in humans, by ingestion of a litre of water or physiological salt solution—led to an appreciable reduction in serum viscosity He also showed that though physiological saline took a longer time than distilled water to reduce the serum viscosity to its minimum level, the reduction achieved with saline was longer maintained The method should be of value for investigating the efficiency of treatment of anhydræmia such as occurs in infantile diarrhœa, cholera, and post operative shock

PNEUMONIA IN CHILDHOOD

PNEUMONIA in children differs so much in clinical manifestations, and particularly in prognosis, from pneumonia in adults that typical examples as judged by adult standards are almost the exception, while the so called atypical forms are the rule This is emphasised by Prof R Pierret,[1] who shows how much our knowledge of this disease has been increased by radiography The illness often runs its course with hardly any of the proper signs in the chest At the onset the rigor is missing, there is no stabbing pain in the side, the cough may be absent, and there is no sputum In fact fever is almost the only constant disturbance Pierret lays stress on the importance of auscultation high up in the axilla where a small patch of fine rales may be discovered

A central pneumonia usually appears in a radiogram as a triangular shadow with its base in the axilla Breton and Christiaens[2] describe several other varieties of triangular shadows and their modifications such as the linear strip across the middle of the right side of the chest when the disease affects the lower part of the right upper lobe Pneumonia in the right middle lobe also modifies the standard triangle and the apex of the lower lobe may present quite characteristic shadows The evidence in favour of a central pneumonia seems to be definitely established by studies of this character Pierret emphasises the benign nature of pneumonia in children, and so does Dr A M Gill[3] in a report from the children's department of the Middlesex Hospital on what he calls "simple pneumonitis" He describes the clinical picture of a child with a persistent cough of recent origin, loss of appetite and sometimes loss of weight The child is listless but at this period of the disease there is no fever Clinical examination shows slight impairment of percussion note over a limited area, with normal or weak vesicular breath sounds and fine rales of a persistent and "sticky" character X ray examination shows some mottled shadowing in the same area and within a week or two, irrespective of treatment all symptoms and signs disappear The child's general condition steadily improves and further radiography shows complete resolution of the pathological process Possibly such a child has passed through a lobar pneumonia of a mild type but Gill is inclined to think this unlikely He looks on the illness as the result of a low grade inflammatory process chiefly affecting the pulmonary alveoli.

A NEW HÆMOPOIETIC FACTOR?

EVIDENCE is accumulating which suggests that the effective hæmopoietic principle in liver is probably a combination of factors with somewhat different actions In a series of papers Jacobson and his colleagues[4] have shown that it is possible to isolate three chemical substances from liver which exert varying effects on hæmopoiesis in animals and man and which to obtain a maximum effect in man must be given together The complex nature of the liver principle is further emphasised though perhaps not clarified in an important paper by Dr Wills and her collaborators in our present issue Wills and Stewart[5] described in 1935 the experimental production of a megalocytic hyperchromic anæmia in monkeys which appeared to be closely allied to tropical megalocytic anæmia Monkeys with this type of anæmia were used in the present investigation, and it was found that it responded well to campolon (a relatively crude liver extract), whereas anahæmin (the purest available preparation) was inactive except in one instance Further it was possible to separate campolon into two fractions according to their solubility in saturated ammonium sulphate One of these, which was thought to contain anahæmin, was inactive in monkeys but curative in human pernicious anæmia, the other was active in monkeys Similar fractionation of yeast extracts also yielded two fractions the soluble one was effective in monkeys while the insoluble was not These observations suggest that the cause of nutritional megalocytic anæmia in the monkey—and probably of tropical megalocytic anæmia—cannot be a simple lack of Castle's extrinsic factor in the diet, as has been usually assumed Nor can the cause be a lack of active principle present in anahæmin, since anahæmin which cures pernicious anæmia does not cure monkey anæmia There seem rather to be at least two hæmopoietic principles in all these extracts (e g liver, autolysed yeast extracts and wheat germ) which are active—some only after incubation with normal gastric juice—both in nutritional megalocytic anæmia and in pernicious anæmia The crude extracts like campolon contain both principles, while the purer extracts like anahæmin contain only one The fact that one monkey reacted to anahæmin given after parenteral injection of the monkey fraction from yeast also suggests that this factor may be needed for normal hæmopoiesis in the monkey but usually the dominant deficiency in the experimental anæmia is of the other—at present unidentified—principle Wills thinks this may be allied to the vitamin B_2 fraction of the vitamin B_2 complex Chemically it appears more closely allied to the substance isolated by Cohn, McMeekin and Minot[6] from liver than to anahæmin or hæmopoietin. Observations on the effect of anahæmin on tropical megalocytic anæmia will throw more light on this complex but important hypothesis Theoretically anahæmin should be inactive in this condition.

THE SURGICAL RELIEF OF IMPOTENCE

IMPOTENCE is often due to flaccidity of the ischiocavernosus and bulbocavernosus muscles they become no longer capable of compressing the efferent vessels To counteract this flaccidity O S Lowsley and J L Bray[7] have devised an operation in which they expose the muscles through a perineal incision and tighten them with catgut sutures Since the muscles are so soft and delicate that sutures rapidly cut through them it is essential that ribbon gut be used Out of 51 patients operated upon 31 have been cured most of the failures being in men over sixty three Lowsley and Bray say that the muscles of men of advancing years are infiltrated with fat and that this may lead to failure of the operation The chief difficulty appears to lie in the selection of suitable patients The elimination of all cases of psychological impotence goes far to restrict the use of this otherwise valuable surgical procedure for in the opinion of many authorities some 80 per cent of cases belong to this class Nevertheless there are cases in which this new technique should be of great service According to the authors the most spectacular cures have been achieved in those who have been rendered impotent by perineal injuries due to operation or by rupture of the urethra by straddle injuries or other violence.

LIMITED QUARANTINE

FROM the beginning of this week most passenger ships bound for New York have been able to go straight to their piers and land passengers without calling at the quarantine station This has been made possible because the U S.A authorities have now put into force the plan drawn up six years ago by the International Health Office in Paris for an international code of signals (see Code vol. 2 Radio p 220) The New York Order of Jan 22nd grants to ships which carry a doctor the facilities envisaged in the plan for the wireless transmission of standard quarantine messages by ships shortly before their arrival in port From the passengers point of view the advantages of the new Order vary according to the class they are travelling Saloon and tourist class passengers are not normally inspected but they will save time Steerage passengers (and presumably the crew) will now be relieved of the march past the quarantine officer It should be noted that the new Order does not confer any rights on passengers it simply grants a privilege at the discretion of the quarantine authorities. A similar system has been in force in the principal British ports for some years and is working satisfactorily Its adoption in New York is a welcome advance since hitherto quarantine in the United States though applied in a fair and impartial manner has been rigorous Other countries will, it is hoped, take note of the relaxation and follow suit

CAMBRIDGE DEGREES

AT Cambridge the degree of M.B is withheld from medical graduates until they have written a thesis When a candidate passes his final examinations in medicine and surgery he receives only the degree of bachelor of surgery and though this is a registrable qualification entitling its possessor to practise medicine surgery and midwifery the fact remains that the official abbreviation *B Chir* conveys little or nothing to the public Thus the Cambridge man is under a disability compared with graduates of other universities until he has found time and opportunity to write an M.B thesis The task is a forbidding one for he is (or was) warned that great weight will be given to evidence of independent observation and reflexion The thesis, he was further told, is an integral and highly important part of the exercises *required for graduation* but in a report issued last week the faculty board of medicine announced that they have decided to recommend its abolition The grounds for this decision are that the theses actually submitted seldom contain anything very valuable that their composition interferes with hospital work and that their assessment imposes an excessive burden on the regius professor of physic who now has much else to occupy him It is proposed therefore that in future the two degrees of M B and B Chir shall be taken simultaneously after passing the final examination and that present holders of the B Chir shall be allowed to proceed to the M B without further test The welcome this news should receive from those it affects will be tempered by an associated suggestion that a higher standard be demanded of candidates presenting theses for the degree of M D

THE CONSEQUENCES OF PHILOSOPHY

THE ordinary man finds it hard to live and breathe in the tenuous atmosphere of pure philosophy To him (and in this he is perhaps basically sound) philosophy is argument, not solution and his interest in the argument is largely determined by his interest in the arguers It is something of a paradox that explorers in the most abstract regions of human thought should be ranked not according to problems they have solved but according to the manner in which they have set about solving them How well Plato realised the personal and dramatic element in philosophy is shown by his choice of the mime as his model for philosophical presentation. When we read in a little book[8] that it is an answer to Planck and Einstein our interest is at once aroused Here is the set for the perennial comedy of the little man and the big man—Eiron and Alazon David and Goliath Socrates and his accusers in Plato the accusers and Socrates in Aristophanes Sancho Panza and Don Quixote my Uncle Toby and my Father Shandy Laurel and Hardy—in this guise has each man in his degree learned wisdom Can the little man make the big man look foolish? If so it is good philosophy and good comedy When the author adds as an afterthought to his title that he is making "a philosophical attempt to mediate between the positivists and the supporters of the metaphysical hypothesis," we but chuckle the more He is like the comedian making irrelevant apologies for his own ridiculous appearance It is thwackings we want not mediation, to mediate is to spoil the sport In point of fact Mr Mundlak gives us a couple of hours good entertainment with himself as Eiron, and such portentous performers as Planck, Einstein, Eddington, and Jeans as alazons There are some nimble mental acrobatics and enough of the thwackings to hold our interest The big man is not allowed to get away with it that the tensor calculus and quantum mechanics makes him any wiser, in the Socratic sense, than the little man, and to see the dénouement of this satisfying little plot, whether it be in a book of philosophy or in a picture house, is always worth the moderate price charged for admission

FLOODS IN THE OHIO BASIN

During the past month floods have caused much inconvenience in parts of Britain and other European countries, but the inundation of an area, comparable to that of Great Britain, in the vast system of rivers which normally finds an outlet into the Gulf of Mexico at New Orleans is a calamity rather than an inconvenience It is reported that 400 people have died, 800,000 homes have been flooded, more than 500,000 people are still homeless and more than 250,000 are marooned in their homes or other refuges—and still the flood is spreading Influenza, pneumonia, typhoid, and even small pox are rife In one town alone over 200,000 have been inoculated against typhoid and the U S Army has taken over the task of removing the population from threatened areas It does not need a vivid imagination to picture the terror and anguish caused by the disaster in the whole valley of the Mississippi and its tributaries, the full effects of which will only become evident when the water recedes leaving slime, filth, corpses, carcasses of animals, relics of homes, with no doubt fresh outbreaks of disease The sympathy of the world will go out to the United States in these appalling conditions

How is such a disaster caused? Why is the greatest river system in the world unable to deal with its waters? Readers of Mark Twain will realise that the Mississippi although a very large river is a very variable one, and the same is true in degree of its tributaries All these rivers bring down vast quantities of silt which, in warm weather, when the flow is slow and the viscosity of the water is low falls out of suspension and causes mud banks, which are continually shifting as flow varies, but cannot shift quickly enough to let a sudden increase in flow get away to the sea or to lower reaches, without causing considerable rises of river level. The banks are notoriously low, but in many places have been raised, either naturally by deposits of silt or artificially by construction of levees or river walls These protect large areas near the rivers from flooding during normal periods of heavy flow, but if they give way under water pressure or if the water rises over them only serve to increase the magnitude of the flood

The comparative mildness of the winter, so far, has led to precipitation of rain rather than snow, and this precipitation has been excessive—it is said that the rainfall in the Ohio Valley for a fortnight has been equal to a normal six months fall. This, instead of being retained in the hills and lowlands of the basin as snow, which, when melted by the increasing sunshine of spring, would normally flow into its natural channels at a steady rate, regulated by the rate of melting, has rapidly run into the rivers and streams The flow has been too rapid for the water to carry away enough silt to increase the capacity of the channels for the greater volume passing through them, so they have overflowed their banks, and where two streams unite the inadequacy of the channels becomes still more marked It is not easy to see what can be done to avoid a recurrence of disaster, since neither rainfall nor temperature can be regulated, and although from some points of view it is unwise to build cities or villages on the banks of rivers liable to flooding, yet the advantages of being on a navigable stream are great, and the sites are likely again to be occupied The construction of levees enables small floods to pass away without serious damage, but accentuates greater ones Probably the proper remedy is to maintain sufficient channels by dredging, but this is costly and would necessitate the formation of a Mississippi Conservancy Board and some interference with the liberty of various States If excessive flow cannot be prevented means must be taken to let the water get away After all the average rainfall of North America is rather less than that of Europe

HALLEY STEWART

The medical profession has good reason to be grateful to Sir Halley Stewart The trust fund which he founded "for research towards the Christian ideal in all social life," and which latterly reached a capital sum of £350,000, was construed so broadly as to include medical research Grants have been made from the Trust to research on tuberculosis cancer, and asthma, and to found a fellowship of £500 for three years tenable in the neurological research unit at Queen square It is understood that the Red House at Harpenden in which he lived is now to become a hospital Halley Stewart was the tenth of a family of fourteen children and lived a life of singular vitality, ended a few days after spending his 99th birthday in apparent good health His elder son is a member of the medical profession, and the name of the younger appears in this week's Honours List in recognition of social service in which he has carried on his father's ideal. Sir Malcolm Stewart was the first Commissioner for the Special Areas of England and Wales

INDEX TO 'THE LANCET," VOL II, 1936

The Index and Title page to Vol II, 1936 which was completed with the issue of Dec 26th, is now in preparation A copy will be sent *gratis* to subscribers on receipt of a post card addressed to the Manager of The Lancet, 7, Adam street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now

---

Royal Society of Edinburgh—A David Anderson Berry gold medal, together with a sum of about £100 will be awarded in July, 1938, by this society for the best work recently produced on the nature of X rays in their therapeutical effect on human diseases A similar award will be made every three years Applications for the prize may be based on both published and unpublished work and should be accompanied by copies of relevant papers They should reach the general secretary of the society 22, George street, Edinburgh, 2 by June 1st, 1938

PRINCIPLES OF MEDICAL STATISTICS

VI —FURTHER PROBLEMS OF SAMPLING: PROPORTIONS

In the previous section the concept of the standard error was developed, and was illustrated by the calculation of the standard error of the mean In addition it was pointed out that every statistical value calculated from a sample must have its standard error—i.e may differ more or less from the real value in the universe that is being sampled For example the standard deviation or measure of the scatter of the observations will vary from sample to sample and its standard error will show how much variability this value is in fact likely to exhibit from one sample to another taken from the same universe In practical statistical work a value which is of particular importance owing to the frequency with which it has to be used is the *proportion* For example from a sample of patients with pneumonia we calculate the proportion who die Let us suppose that from past experience *covering a very large body of material* we know that the fatality rate of patients with pneumonia is let us say 20 per cent (the actual figure from the point of view of the development of the argument is immaterial) We take over a chosen period of time a randomly selected group of a hundred patients and treat them with serum Then presuming that our sample is a truly representative sample of all patients with pneumonia—e g in age and in severity—we should observe if serum treatment is valueless about 20 deaths (it may be noted that we are also presuming that there has been no secular change in the fatality rate from pneumonia) We may observe precisely 20 deaths or owing to the play of chance we may observe more or less than that number Suppose we observe only 10 deaths is that an event that is likely or unlikely to occur by chance with a sample of 100 patients? If such an event is quite likely to occur by chance then we must conclude that serum *may* be of value but so far as we have gone we must regard the evidence as insufficient and the case unproven. Before we can draw conclusions safely we must increase the size of our sample If on the other hand such an event is very unlikely to occur by chance we may reasonably conclude that serum is of value (that is of course having satisfied ourselves that our sample of patients is comparable with those observed in the past in all respects except that of serum treatment) Before we can answer the problem as to what is a likely or an unlikely event we must determine the standard error of a proportion—i e the variability of a proportion in samples of a given size taken from the same universe Presuming the treatment is of no help then the fatality rate we should observe on a very large sample is 20 per cent (or nearly that) How far is the rate likely to differ from that figure in samples of different size?

SAMPLE OF ONE

If our sample comprises only one patient the fatality rate may be either 0 or 100 per cent; if the patient dies the fatality rate is greater than that of past experience If the patient recovers this is obviously not very convincing evidence in favour of our treatment for according to past experience 4 out of 5 patients are likely to recover without our treatment (20 per cent or only 1 in 5 die)

SAMPLE OF TWO

If the sample is increased to two patients, three events become possible (i) both may recover (ii) 1 may recover and 1 may die (iii) both may die

On the basis of past experience we can calculate the probability of each of these events occurring (i) The chance that one may recover is 4/5 the chance that the other may recover is also 4/5 the chance that *both* will recover is the product of these two independent probabilities—i.e 4/5×4/5=16/25 (ii) The chance that one patient will recover is again 4/5 the chance that the other will die is 1/5; the chance that *both* these events will occur is therefore 4/5×1/5 but this value must be multiplied by 2 for the event can happen in two different ways—viz patient A may live and patient B die or patient A may die and patient B live The probability therefore of observing one recovery and one death is 2 (4/5×1/5)=8/25 (iii) Finally the probability of each patient dying is 1/5 and of both patients dying is 1/5×1/5=1/25 We can tabulate these values as follows

Event	Probability of event	Fatality rate per cent
Both patients recover	16/25 = 0·64	0
One patient recovers one dies	8/25 = 0·32	50
Both patients die	1/25 = 0·04	100
—	25/25 = 1·00	—

The total probability is 1 for there is no alternative to these three events Clearly the only event that suggests that our treatment is of value is the recovery of both patients when the fatality rate is 0 compared with the 20 per cent of past experience The death of one patient in a sample of two gives a fatality rate of 50 per cent. and of both patients one of 100 per cent both rates being worse than past experience But the more favourable event the recovery of both patients is obviously an event which is more likely than not to occur by chance; it may be expected to occur 64 times in 100 trials with 2 patients even if the treatment is ineffective Therefore with a single sample of 2 patients and a normal fatality rate of 20 per cent the chance that both will recover is large and if such a result is observed we cannot deduce from it that our special treatment is of value

SAMPLE OF THREE

If we increase the sample to three patients four events become possible (i) all 3 may recover (ii) 2 may recover and 1 die (iii) 1 may recover and 2 die (iv) all 3 may die

The probability of each event can be calculated as before (i) The chance of the recovery of all three patients is 4/5×4/5×4/5=64/125 (ii) The chance that two may recover and one die is 4/5×4/5×1/5 this must be multiplied by 3 for this event can happen in three different ways since any one of the three patients may be the one to die; this equals 48/125 (iii) The chance that one may recover and two may die is 4/5×1/5×1/5 also multiplied by 3 for this event can also happen in three ways this equals 12/125 (iv) Finally the chance that all three may die is 1/5×1/5×1/5 an event which can happen *only in one way, and equals 1/125* Tabulating we have

Event	Probability of event	Fatality rate per cent
Three recover	64/125 = 0 512	0
Two recover one dies	48/125 = 0 384	33 3
One recovers two die	12/125 = 0 096	66 7
Three die	1/125 = 0 008	100 0
—	125/125 = 1 000	—

The only event that favours our treatment is, again, the recovery of all the patients Any other event gives a higher fatality rate than that of past experience—viz , 20 per cent But the recovery of all 3 patients is an event which is quite likely to occur by chance , it may be expected to occur 51 times in 100 trials with 3 patients even if the treatment is ineffective With a single sample of 3 patients, therefore, the chance that they will all recover is large, and again we cannot deduce that our special treatment is of value

SAMPLE OF FOUR

If we increase the sample to four patients five events become possible, (i) all four may recover, (ii) three may recover and one die, (iii) two may recover and two die, (iv) one may recover and three die, (v) all four may die

What is the probability of each of these events on the basis of past experience ? (i) The chance that all four recover is $4/5 \times 4/5 \times 4/5 \times 4/5$, this event can happen in only one way, and the probability equals 256/625 (ii) The chance that three recover and one dies is $4/5 \times 4/5 \times 4/5 \times 1/5$, multiplied in this case by 4, for there are four different ways in which this event can happen , any one of the four patients can be the one to die The probability of this event is also, therefore, 256/625 (iii) The chance that two recover and two die is $4/5 \times 4/5 \times 1/5 \times 1/5$, multiplied in this case by 6, for there are six ways in which the event can happen For if the patients are named A, B, C, and D, the following events are possible

Recover	*Die*
AB	CD
AC	BD
AD	BC
BC	AD
BD	AC
CD	AB

The probability of this event is, therefore, 96/625 (iv) The chance that only one recovers and three die is $4/5 \times 1/5 \times 1/5 \times 1/5$, multiplied, as before, by 4 (for any one of the four may be the fortunate one to recover) , this equals 16/625 (v) Finally, the chance that all 4 will die is $1/5 \times 1/5 \times 1/5 \times 1/5 = 1/625$ Tabulating

Event	Probability of event	Fatality rate per cent
All four recover	256/625 = 0 4096	0
Three recover one dies	256 625 = 0 4096	25
Two recover two die	96/625 = 0 1536	50
One recovers three die	16 625 = 0·0256	75
All four die	1 625 = 0 0016	100
—	625/625 = 1·0000	—

Once more the recovery of all the patients is the only result which gives a fatality rate lower than that of past experience, but this, again, is an event quite likely to occur by chance , it may be expected to occur nearly 41 times in 100 trials with 4 patients even if the treatment is ineffective

SAMPLE OF TEN

We can with samples of any size calculate by these methods the probability of favourable results occurring merely by chance , as the sample increases in size, however, the calculations become progressively more laborious But clearly we need not calculate *all* the probabilities If, for example, we treat ten patients then the only results which are better than that of past experience are those which give no patients at all dying or only 1 patient dying—i e , fatality rates of 0 or 10 per cent If two of the ten patients die the fatality rate is normal according to past experience, 20 per cent , and if three or more die then it is higher than that of past experience The probability of all 10 patients recovering equals $(4/5 \times 4/5 \times 4/5 \times 4/5 \times 4/5 \times 4/5 \times 4/5 \times 4/5 \times 4/5 \times 4/5) = (4/5)^{10}$ = 0 1074 , the chance of 9 patients recovering and 1 dying $= \{(4/5)^9 \times (1/5)\} \times 10$ (for any one of the 10 may be the one to die) = 0 2684 Either of these events gives a result better than past experience, and the probability of observing by chance one or the other is the *sum* of the two probabilities, or 0 1074 + 0 2684 = 0 3758 In other words we should expect to get a better result than past experience nearly 38 times in 100 trials with 10 patients even if serum treatment were quite ineffective Obviously in a single sample of 10 patients a result better than that of past experience is still not an unlikely event to occur by chance, and from such an observation we cannot deduce that serum has reduced our fatality rate

SAMPLE OF A HUNDRED

If now we return to our original problem—namely, a sample of 100 patients of whom only 10 die—the probability we need is that with which this result *or a better one* might be expected to occur even if our treatment with serum were quite ineffective—so that we ought to have observed 20 deaths on the basis of past experience It is *possible* to calculate this by just the same means as were applied to smaller numbers Tabulating we have the results shown on the top of the opposite page

The sum of the probabilities will give the number of times we might expect to reach a result as favourable as the one we have observed, or even more favourable, merely as a result of chance This sum is 0 0057, and we may conclude that only 57 times in 10 000 trials with a hundred patients would such a result turn up merely by chance Such a result, therefore, suggests that our treatment favourably influenced the survival rate But this calculation is extremely heavy and some shorter method is in practice essential

THE GENERAL CASE

Let us return to the tabulation regarding two patients This shows, if we write it in percentage *form* that if we had 2 patients in each of 100 hospitals the fatality rate would (on the average) be 0 in 64 of these hospitals 50 per cent in 32 of the hospitals, and 100 per cent in 4 of them From these figures we can calculate the *mean* fatality rate in the 100 hospitals and the *standard deviation* of the frequency distribution round that mean The mean fatality rate is $(64 \times 0) + (32 \times 50) + (4 \times 100) - 100 = 20$ per cent and the standard deviation will be found, calculated by the ordinary methods, to be 28 3 A similar calculation

Event.	Probability of event	Fatality rate per cent.
All 100 recover	$(4/5)^{100}$ = 0·00000000020	0
99 recover 1 dies	$(4/5)^{99} \times (1/5) \times 100$ = 0·00000000 00	1
98 recover 2 die	$(4/5)^{98} \times (1/5)^{2} \times 4,950$ = 0·000000063	2
97 recover 3 die	$(4/5)^{97} \times (1/5)^{3} \times 161,700$ = 0·000000514	3
96 recover 4 die	$(4/5)^{96} \times (1/5)^{4} \times 3,921,225$ = 0·0000031	4
95 recover 5 die	$(4/5)^{95} \times (1/5)^{5} \times 75,287,520$ = 0·00001495	5
94 recover 6 die	$(4/5)^{94} \times (1/5)^{6} \times 1,192,052,400$ = 0·00005928	6
93 recover 7 die	$(4/5)^{93} \times (1/5)^{7} \times 16,007,560,800$ = 0·0001900	7
92 recover 8 die	$(4/5)^{92} \times (1/5)^{8} \times 186,087,894,300$ = 0·0005 81	8
91 recover 9 die	$(4/5)^{91} \times (1/5)^{9} \times 1,902,231,808,400$ = 0·001478	9
90 recover 10 die	$(4/5)^{90} \times (1/5)^{10} \times 17,310,309,456,440$ = 0·003363	10

These multipliers are the number of different ways in which the event could happen. Clearly there are 100 ways in which 1 could die and 99 survive; there are 4,950 ways in which 2 could die and 98 survive, and so on.

for three patients gives a mean fatality rate in the 100 hospitals of 20 per cent. and a standard deviation round it of 23·1; for four patients the mean is 20 per cent. and the standard deviation is also 20·0. The *mean* fatality rate in samples of each size—viz., 20 per cent.—is the value, it will be noted, that we expect to reach according to past experience; but in the individual sample we shall not necessarily observe this mean value, for round it there will be a variability in the fatality rate from sample to sample due to the play of chance measured by the standard deviation and decreasing as the size of the sample increases. If we could calculate this standard deviation *without* having to find the different probabilities for each event we should have a measure of the variability that will occur by chance in the fatality rate in samples of different sizes. This calculation is, in fact, very simply made. If on the basis of past experience we expect 20 per cent. of patients to die and 80 per cent. to recover then the standard deviation round that expected 20 per cent. will be in samples of 2 equal to the square root of $\frac{20\times80}{2}=28·3$, in samples of 3 equal to the square root of $\frac{20\times80}{3}=23·1$ and in samples of 4 equal to the square root of $\frac{20\times80}{4}=20·0$. These values are the same as those found above by the longer calculation. In more general terms the standard deviation or, as it is usually termed, the standard error of a percentage is $\sqrt{\frac{p\times q}{n}}$ where p is the percentage of individuals belonging to one category (e.g., alive), q is the percentage in the other category (e.g., dead) and n is the number of individuals in the sample. We can therefore readily find the standard error of the percentage—i.e., the variability it would show from sample to sample—in samples of 100 or more patients. With 100 patients the standard error is $\sqrt{\frac{20\times80}{100}}=4·0$. In other words on the basis of past experience we should expect 20 of the 100 patients to die but in different samples of that size we should not always observe that proportion dying; the proportions observed in samples of one hundred will be scattered round 20 with a standard deviation of 4. We know (as was shown with the standard error of the mean in the previous section) that there will be relatively very few samples in which the proportion actually observed will differ by more than twice the standard error from the mean expected value. For instance with 100 patients we expected 20 per cent. to die but as this percentage has in samples of this size a standard error of 4 we might by chance observe a value in a single sample as high as $20+2(4)=28$ or as low as $20-2(4)=12$. Actually we observed a value of 10 per cent. This is beyond the value that might, *according to our criterion*, be likely to arise by chance and, *other things being equal*, we may deduce that it *appears likely* that serum treatment lowered the fatality rate. The italicised words must be emphasised. It must be recognised that we are weighing probabilities, never, as is sometimes suggested by non-statistical authors of medico-statistical papers, reaching mathematical proof. A difference between the observed and expected values *may* be a "real" difference (in the sense that the treatment was effective) even though it is not twice the standard error, but the calculation shows that the hypothesis that the difference has occurred by chance is equally valid. If on the other hand the difference between the observed and expected values is, say, four times the standard error this does not "prove" that it is a "real" difference; it may still be the result of chance. But the calculation shows that the hypothesis that it is due to chance is unlikely to be true, for such a chance difference is a rare event. The advantage of the calculation is that the investigator is thus enabled critically to estimate the value of his own results; he may be prevented from wasting his time by erecting some elaborate superstructure of argument on a difference between two averages (or proportions) which is no greater than a difference that might well be obtained on drawing two random samples from one and the same record (C. U. Yule: Industrial Health Research Board Report No. 28, 1924, p. 6).

Finally, presuming that the difference recorded between the observed and expected values is more than would be expected from the play of chance, then we must consider carefully whether it is due to the factor we have in mind—e.g., serum—or to some other factor which differentiated our sample—e.g., age or severity of disease—from the general population of patients. Where, as Yule expresses it, "some particular interpretation is rather attractive the investigator must be the more on his guard."

For the sake of clarity the standard error of the proportion has been deduced on the basis of a figure known from past experience In actual practice such a figure is not often available or may be an unsatisfactory criterion of the expected level in the observed sample, owing to some secular change The more usual procedure is the comparison of two percentages recorded over the same period of time in an experimental and a control group The development of this test is discussed in the next section

Summary

A statistical value which is of particular importance from the frequency of its use, is the proportion, or percentage By simple means the standard error of this value can be calculated, that is the amount of variability it will show from sample to sample for samples of different sizes The relation of the difference between an expected percentage and an observed percentage to this standard error shows whether that difference is likely or unlikely to have arisen merely by chance As a convention we take twice the standard error as a criterion If the difference is more than twice the standard error it is said to be "significant"—i e, unlikely to have arisen by chance, if it is less than twice the standard error the difference is said to be "not significant"—i e, it may easily have arisen by chance The test always involves weighing probabilities, and can never amount to proof in the logical sense The test can give no information as to the *origin* of the difference beyond saying that chance is an unlikely explanation

HEARING-AIDS

A REPORT TO THE MEDICAL RESEARCH COUNCIL

THE accurate investigation of deafness is a product of the recent advances in sound reproduction and recording which have followed telephone engineering and broadcasting The application of these to the alleviation of deafness is not a simple one, for individual deaf persons vary in the extent to which they are deaf to different pitches of the auditory range Dr and Mrs Ewing and Dr Littler,[1] who have prepared a report which has been published by the Medical Research Council, are pioneer advocates in this country of group hearing aids for classes of severely deaf children, and they show that these aids are safe to use and do not cause any deterioration in hearing

They open their report by summing up the problem to be considered as follows —

(1) How does the ear of a partially or severely deaf patient behave when stimulated by loud sounds and to what extent can speech be made intelligible to him by amplification ?

(2) What are the characteristics of the most efficient type or types of aid ?

(3) What tests will ensure that the patient may be effectively advised as to what, if any, type of aid is suitable to his individual needs ?

They emphasise the first of these three questions, since the deaf patient must be supplied with a portable instrument which will enable him to follow the speech of any speaker under conditions which are little, if at all, subject to his control and often most unsuitable for sound reproduction by any existing mechanical means It is known that no matter how short the duration of sound, there is an average upper limit of intensity at all audible frequencies for people with normal hearing Intensities beyond this upper limit cause discomfort or pain, and the limit is therefore sometimes called the threshold of feeling The area between this and the threshold of audibility is the auditory sensation area This area is restricted in the deaf patient in the sense that his defect prevents him from hearing a sound of intensities and often of frequencies which are audible to the normal ear No hearing aid can restore the capacity to respond to sound over the lost range A highly sensitive aid may amplify a whisper to such an extent that it rises above the raised threshold of audibility, but that part of the area for which he is deaf remains dead ground for all time The normal ear can respond effectively to sounds ranging from a whisper (something like 15–30 decibels) to that of speech so loud as to approach the threshold of feeling (130 decibels) Efficiency in the supply and use of hearing aids requires, in the first place, the measurement of the patient's threshold of minimum audibility for speech This is most conveniently expressed in terms of the standard intensities used to give levels of loudness for speech, music, and noise For example, a patient who is so deaf that his threshold of audibility for speech is 60 decibels above that of normal listeners cannot be expected to follow average *mezzo forte* conversation at a distance of three feet, for such conversation has an intensity value of approximately 55 decibels above the normal threshold of audibility A speech threshold 100 decibels above normal implies that there is little capacity to hear speech even uttered in a loud voice close to the ear Thus the measurement of the threshold of audibility for speech shows the extent to which the deafness interferes with the ability to follow speech, and it also indicates the degree of amplification needed to bring sounds of different levels of loudness within the patient's range of hearing

Speech is, of course, a mixed sound, but nevertheless the threshold of audibility for it can be reliably deduced from the threshold for pure tones, and these can be ascertained by means of a pure tone audiometer or beat-tone oscillator Generally the speech threshold is within 5–10 decibels of the lowest reading for pure tones Experiments were made both by air conduction and by bone conduction The subject was seated in a sound proof room and signalled to the operator in another room when he could hear the sound When speech was being tested, and not pure tone only, the speaker sat inside the sound proof room with his lips twelve inches from a microphone The word "bah" was used for pure hearing, and various single syllable words closely resembling each other, or meaningless double syllable words were used to test intelligibility Only two of the patients tested had sufficient acuity for average *mf* conversation at three feet For one of them *mf* conversation was 10 decibels quieter than a whisper would be to a normal ear He was the least deaf of the nine patients, but a course of lip reading lessons combined with the use of a high quality amplifier for lectures (he was a university student) caused a marked improvement in his examination results Two patients were so deaf as to be unable to hear any speech unless it was louder than an *ff* voice and less than three feet from the ear To them the noise in weaving sheds (00 decibels) for which normal subjects need ear defenders is very little above the threshold of audibility

[1] A W G Ewing M A Ph D I R Ewing M Sc and T S Littler M Sc Ph D (Department of Education of the Deaf, Victoria University of Manchester) The Use of Hearing Aids Medical Research Council Special Report Series No 219 1937 Pp 40 9d

DANGERS AND VALUES OF HEARING AIDS

It is important to know whether patients suffering from aural lesions should listen to very loud sound Very large intensities are often necessary if they are to hear speech with a maximum degree of intelligibility U Yoshi has shown that excessive stimulation may cause degeneration of the cochlea and it is commonly believed that the noise in boiler works induces deafness In addition to the possibility of damage to the ear there is the fact that loud sound not physically injurious is often psychologically objectionable The degree of loudness physiologically undesirable is ascertainable by quantitative experiment the *sensation is not merely objectionable* but makes the withdrawal of the ear from the receiver a reflex and inevitable act. Auditory fatigue is experienced by normal subjects when they listen to pure tones at large intensities for two minutes or more but deaf subjects seem less susceptible than the normal to this form of fatigue The magnitude of the fatigue is related to the duration of the stimulus and as the loudest components in speech vowels never last longer than half a second the fatigue does not appear when the speech is amplified Daily use of a powerful hearing aid for a long time has not been followed by any change in auditory acuity

The authors of the report think it very desirable to devise a standardised test for intelligibility of amplified speech The most reliable test stimuli are standard lists of syllables numbers and familiar words can be recognised when very imperfectly heard Such a test has considerable diagnostic value for speech cannot at present be made fully intelligible by any known aid when deafness to high frequencies is associated with cochlear and nerve lesions Other partially and severely deaf patients can be enabled to hear speech with approximately 100 per cent intelligibility

It is possible to measure the effective amplification of various hearing aids; the most satisfactory results are yielded by those instruments which approach most nearly to uniform amplification over the frequency range 200 ~ to 8000 ~ Valve amplification is indispensable if this is to be attained. Non valve battery aids give some help to a number of patients but their usefulness is greatly limited by their low amplification and the undesirable character of their frequency response Most non valve aids reduce the intensity of sounds of high frequency and so can never compensate for severe deafness to upper tones Bone-conduction receivers show the same limitation and are not in their existing form an economical means of using the output of an amplifier All electrical aids present the problem of background noise but in varying degrees depending on the ratio of noise to sensitivity of the microphone and amplifier in use Background noise can be measured in decibels and the measurement shows whether any particular subject will hear it or not Tests on 158 adult patients attending a clinic during eighteen months showed that 01 could obtain a good deal of help from a portable valve aid 18 from non valve battery aid 2 from bone conduction battery aid, and 16 from speaking tubes only while 28 could get no help from any aid An aid is most effective in a quiet room with good acoustic qualities and when listening to clear speakers. Even when the most efficient type of aid available is used lip reading is essential if the deaf person is to suffer the minimum disability from his deafness.

THE DEAF CHILD

The authors have also made a prolonged study of deafness in children They tested 236 children attending a school for the deaf and found that no less than 140 of them could benefit educationally from hearing aids Of 27 children attending elementary schools or special schools for the mentally retarded and not making good progress 24 were found to be deaf in varying degrees and were of the type which could make good progress if they were referred to a school for the deaf Only 3 were actually mentally retarded It has been found impossible to make pure tone tests of pre school children owing to their lack of interest and inexperience in listening to meaningless sounds but a series of tests have been devised *in which the young child learns to play in* response to sounds These tests give reliable but non quantitative evidence of the degree of deafness and the type of ear training on which to base the development of speech Hearing aids for class teaching are in use in a number of schools for the deaf and a comparison has been made between classes which have received systematic teaching by combined hearing aid and lip reading and those without these facilities The comparison is even more satisfactory than had been anticipated It is essential in class teaching that the teacher should speak close into the microphone and therefore a class amplifier is better than individual aids used at a distance from the teacher The class amplifier is also an advantage in discussions and conversation classes The child is in a different position from the adult His development in speech and his educational progress depend on the acquisition of new ideas associated with a new language and faithful reproduction of the highest quality is therefore vital. Education and speech development normally advance together and the quality of the hearing aids for educational *purposes affects results to a very marked degree*

Dr and Mrs Ewing and Dr Littler conclude that the conditions under which hearing aids are supplied to the public should include (*a*) tests of the patient s response to pure tones of the speech range (*b*) a standardised articulation test of the patient s capacity to respond to amplified speech under controlled conditions (*c*) articulation tests with the instrument which it is proposed to supply to the patient for a period of trial (*d*) familiarity on the part of those responsible for the supply of aids with the physical characteristics of each type of instrument especially its frequency response and effective amplification

MEDICINE AND THE LAW

Hire Purchase Research

If any medical practitioner has been persuaded to sign a contract with the Consolidated World Research Society Ltd. he may be interested in the experiences of one who decided to cancel his bargain This limited company offers an encyclopædia on the instalment system and like other sellers of similar publications, employs canvassers to commend its merits to potential buyers. The books are not the sole inducement. The purchaser who signs the contract obtains also certain additional privileges of advice in research. Exactly what these privileges may be is a question which seems to be left to the canvassers to answer. If the usual printed copy of the agreement is signed, the subscriber thereby requests delivery of "The Consolidated Encyclopædia, comprising ten volumes in de luxe artcraft binding." Simultaneously he asks that his name be enrolled as a subscriber to the following services: (a) perpetual illustrated quarterly extension service for a period of ten years, (b) binders for the quarterly extension service, and (c) registered membership of the Consolidated World Research Society Ltd. for ten years. For all this he agrees to pay something down forthwith, and specified further instalments at specified intervals until the amount reaches £19 10s. "which covers the total cost of all the benefits described above." Then comes a paragraph which stipulates that the contract is not subject to cancellation, and makes the purchaser declare "I have entered into this contract solely upon the terms and conditions herein contained and irrespective of any representations made to me by any of your representatives." This frank provision, which the subscriber has possibly not studied before signature, leaves the company's canvassers a free hand to promise every kind of advantage to the purchaser. In the circumstances it would be only natural if they were very promising salesmen. If our readers should ask what are the profitable features of "registered membership" of this limited company, we can find little guidance for them on the face of the printed document. There may well be something more explicit in the eloquence of the canvassers whose persuasiveness the contract so ruthlessly repudiates. If our information be correct, the verbal inducements include the promise of consultative facilities and the prospect that the subscriber, instead of having to wait many years to establish himself in his profession, will meet with accelerated recognition and will be brought into touch with prominent figures in the world of medical research and medical practice. These suggestions seem to gather some confirmation from a paragraph marked "Important" on the back of the printed contract. The paragraph is somewhat vaguely headed "Information for Service Department"; it could be argued that it does not commit the company to any legal undertaking. "Much," it says, "of the value of the extension service and advice privileges for which you have enrolled will come from the personal relation that will develop between us. So that our Research Staff may come to know you better, we suggest as time progresses, that you keep us posted regarding the subjects in which you are particularly interested." The privileges of membership, we repeat, so far as they depend upon the printed agreement, lack both definition and value. One, at least, of the medical subscribers has placed on record his experience of them. He signed the printed contract and paid a deposit of £1 10s., but, being dissatisfied with the representations made to him by the company's agent, he afterwards repudiated the agreement. The company issued a summons in the county court, claiming £18 as the balance due for purchase of the encyclopædia. The defendant doctor, having taken the advice of the Medical Defence Union, put in a defence on oath in which he gave his own version of the transaction as follows:

"I accepted the verbal offer of the representative of the plaintiffs that for a fee of £1 10s. down and ten subsequent yearly payments of £1 10s. each, the plaintiffs' society would answer any research questions by me up to a specified number per annum, and I made the first payment of £1 10s. to him accordingly.

"I discovered I had been fraudulently deceived and misled by the plaintiffs' representative, and applied to the plaintiffs for a return of the £1 10s. paid by me.

"Any contract set up by the plaintiffs as made by me to purchase any encyclopædia or other books was obtained by fraud and wilful misrepresentation by the plaintiffs' representatives."

It must have been an uncomfortable reply for the Consolidated World Research Society Ltd. to receive. No commercial undertaking can relish so whole hearted an allegation that its agents are obtaining business for it by fraud. The defendant doctor, however, was not given the opportunity to repeat his story in court. A few days before the date fixed for hearing, notice to discontinue the claim was filed on behalf of the society. If the society feels it has been unlucky in devising a system of enterprise which permits such allegations to be made, it will doubtless reconsider its method of doing business.

PARIS

(FROM OUR OWN CORRESPONDENT)

THE COMMERCIAL IRRADIATION OF FOODS

SOME rather unkind things were said at a recent meeting of the Academy of Medicine by Dr. E. Lesné about the so called irradiation of various foods by enterprising manufacturers who seem to have rushed in where scientists have been so many tender footed Agags. At the present time in France you may not only buy irradiated milk and flour over the counter, but also pastries, sugar, chocolates, and so forth, all supposed to have been pumped full of various vitamins. It was pointed out that these preparations are either inactive, in which case their usefulness is limited to the vendor, or they are active, in which case they may be potent for evil as well as for good, and ought, therefore, to be sold only on the prescription of a doctor. It seems that, as a rule, these preparations are in fact more or less irradiated, however little may be known of the dosage, the possible harm being anticipated from over dosage, and the loss of other properties, presumably beneficial, entailed in the processes of irradiation, for it was suggested that, with the increase of vitamin D, the irradiated substances may lose some or all of their vitamins B and C. The whole subject is, indeed, bristling with so many problems still unsolved that the Academy of Medicine adopted a resolution that foods artificially enriched with vitamin D must not be on sale except in a pharmacy, and then only on a medical prescription. Such preparations must not be sold until their freedom from toxic substances is established and they can be guaranteed not to be injurious to the consumer. A further stipulation was that the vitamin content of such preparations should be accurately gauged by biological tests made regularly in an approved laboratory. It remains to be seen how far the adoption of this resolution by the most important medical body in France will inhibit the activities of manufacturers straining at the leash in their efforts to give potentially suffering humanity the benefits of recent research with the minimum of delay and the maximum of faith.

A SUIT FOR NEGLIGENCE

Certain interesting sidelights on the responsibilities of doctors, nurses, and chemists were thrown by a recent lawsuit arising out of a death from tetanus Having run a rusty nail into her foot while walking in her garden in a suburb of Paris a woman of 40 sought the advice of a doctor who on the day of the accident prescribed an injection of antitetanus serum He instructed a so-called nurse to give this injection The husband took the prescription to a pharmacy where he was given by mistake a bottle of anti diphtheria serum. While she was about to give the injection the nurse noticed the mistake and while she hesitated the husband insisted Prick her for it will do her good all the same Though she saw the doctor next day the nurse omitted to mention this matter When five or six days later complications appeared, the doctor was summoned and found evidence of tetanus He was surprised at the impotence of the injection he had prescribed but no one informed him of the mistake that had been made An urgent prescription for antitetanus serum was sent to the same pharmacy where the same mistake was repeated this time four bottles of antidiphtheria serum being supplied This was too much for the nurse who insisted on these bottles being changed for others containing veritable antitetanus toxin Its injection was, however incapable of averting death eight days after the accident It transpired in the course of the legal proceedings that the vendor of the first supply of serum was not a fully qualified chemist he was not even a student in pharmacy The nurse also proved to be a housekeeper bereft of any nursing certificates or diplomas In the first instance the vendor of the first lot of serum was sentenced to six months in prison the pharmacist himself (it was he who had sold the second lot of serum) to four months the doctor to a small fine while the nurse was acquitted On appeal negligence was imputed to all concerned the nurse included. Though the terms of imprisonment were not imposed the publicity given to this case should prove salutary in many ways not least in the matter of the employment of undependable and untrained persons in responsible positions.

SELF ADVERTISEMENT IN AUTOBIOGRAPHY

A communiqué recently issued by the Federation des Syndicats Médicaux de la Seine is a perhaps praiseworthy attempt to bridle the enterprise of those of its members who from time to time are solicited for biographical sketches of themselves with or without photographs also of themselves The recipients of these solicitations are informed that the character of the publication in which their autobiographies will appear is strictly scientific but that the exigencies of printing &c necessitate the payment of a subscription For even in the world of science you must pay your way The unappreciative attitude of the Fédération with all necessary clarity gives its considered opinion that such autobiographical activity constitutes more or less disguised self advertisement is contrary to the rules of ethics and is justly condemned by the medical profession

IRELAND

(FROM OUR OWN CORRESPONDENT)

MEDICAL RESEARCH IN THE IRISH FREE STATE

THE scheme to establish and endow medical research in the Irish Free State appears at length to be nearly accomplished. It was announced last week that the certificate of incorporation of a Medical Research Council had been issued It is now more than two years since a draft scheme was submitted to the Minister for Local Government and Public Health for his approval by a representative committee which had been formed on the initiative of the Royal Academy of Medicine in Ireland In accepting the scheme with certain amendments, the Minister has also sanctioned as a temporary measure a grant of £10 000 per annum from the Sweepstake Funds Should the council justify its existence by successful activity it is hoped that in the future provision may be made for the establishment of a Research Institute Funds will for the present be devoted to giving scholarships at home and abroad and to grants for specific purposes The council is to consist of eight persons, the chairman to be appointed by the Minister and the other seven by the several universities and medical schools and the Royal Academy of Medicine The chairman's name has not yet been announced but the following have been nominated by the several bodies named University of Dublin Prof J W Bigger University College Dublin Prof Henry Moore University College Cork, Prof. J M O Donovan University College Galway Prof. J F Donegan Royal College of Physicians of Ireland Prof. T G Moorhead Royal College of Surgeons in Ireland Prof. W J E Jessop and Royal Academy of Medicine in Ireland Dr J W McGrath.

BOOKS FOR HOSPITALS

Some months ago the Minister for Local Government and Public Health had given his approval to a grant from Sweepstake Funds for the purpose of providing books for the reading of hospital patients A committee for the purpose has now been appointed by the Minister and the first meeting was held on Feb 2nd

TRINITY COLLEGE DUBLIN MEDICAL SCHOOL

There have been some changes in the anatomy department at Trinity College Dublin and the abolition of the separate dissecting room for women in the anatomy department removes a relic from the pioneer days of women medical students Since last term all have used a joint dissecting room and the vacated space has been converted into a reading room. Among the new appointments are those of Dr E D Adrian of Cambridge who will deliver the John Mallet Purser lectures this year and Dr I B Alabaster who has been appointed to the Mary Louisa Prentice lectureship in ophthalmology

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION —A special course for the primary F R C S examination will be given at the Infants Hospital on Mondays Wednesdays and Fridays at 5 15 P.M (physiology) and 6 30 P.M (anatomy from Feb 22nd to May 24th) An all-day course in medicine surgery and gynaecology will be given at the Royal Waterloo Hospital from Feb 22nd to March 6th A week-end course in children's diseases will be held at the Princess Elizabeth of York Hospital on Feb 20th and 21st M R C P courses will be held as follows: clinical and pathological course National Temperance Hospital (Tuesdays and Thursdays 8 P.M Feb 16th to March 4th); chest diseases Brompton Hospital (5 P.M twice weekly Feb 22nd to March 20th) heart and lung diseases Royal Chest Hospital (Mondays Wednesdays and Fridays at 8 P.M March 1st to 26th); neurology West End Hospital for Nervous Diseases (afternoons March 8th to 20th) An all-day course in proctology will be given at St Mark's Hospital (March 1st to 6th)

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM A ROVER

I

FREEDOM to indulge oneself in "unfettered thoughts" was too great a temptation to resist Here's "fun," I said to myself, using a word which we grown ups have borrowed from our children Anonymity for several months, too, and with a fair chance that any curiosity which may have been aroused at the moment the article was read will have died before the half yearly index appears And "tut, tut" was a sufficient answer to the kill joy spirit which held up the bogy of a supposition that some all too clever reader might divine, from internal evidence—either by the text or by the style (or lack of it)—who the writer really was "But that's fun, too, for some people," added the spirit of mischief, and the recollection that I had myself played this game with some, nay most, of the "Grains and Scruples" that had preceded these of mine—not being a cross word puzzle fan—egged me on rather than restrained me There's "A Chronicler," for example, whose name is now out, who else could have produced those four articles but the doyen of medical writers, he who might appropriately say in his defence, if charged with not coming within the category of "doctors in various occupations," what Iphicrates said when he was charged with not being any particular sort of soldier, "I am not indeed, I confess, but I am he who commands all of them and employ them as occasion serveth."

* * *

"A Chronicler" discusses the important question of educating the lay public on matters of health, and he has in mind, in particular, the medium of the lay press I want to unfetter a few thoughts on this subject

We may just as well face the basic facts, which seem to me to be these The average reader lusts to know things about diseases and remedies *when these concern himself* I agree that matters of epidemiology and statistics, and even the latest advances in bio chemistry or bacteriology, interest him much less But not only must the matter served up to him, if it is to be popular, have the news value incident upon its application to his own body, there must be news value in the personality of the man or woman who writes it This means that the identity of the writer shall be revealed, and here comes the conflict with the traditions of the profession in this country So long as these traditions remain—and most of us believe it to be in the public interest that they should remain—so long will the impasse last

* * *

The proprietor of a daily paper who recently approached a well known doctor on this matter, and who thought the veto upon signed articles dealing with health matters was "all my eye" was offered a series of articles by a panel of medical men who should be experts upon the various subjects dealt with He was told that he might preface the articles by publishing a list of the names on the panel, but that no individual article would be signed. Payments for the articles were to go to the Royal Medical Benevolent Fund His reply was that he would pay five guineas each for articles contributed on this basis and one hundred guineas for each article if it were signed *and if he might choose the writer*

A short time ago the B B C introduced into its programmes a series of talks upon health The various subjects with which the speakers dealt were all of them calculated to interest the man in the street The speakers were chosen by a high official at the Ministry of Health, but the names of the speakers were not published The name of the doctor who introduced the series, however, *was* published. It was presumed that he would not deal with any specific disease, and indeed the text of his talk was "vetted," no doubt with this embargo in mind.

* * *

They do this sort of thing very differently in America as, of course, they do many other things differently! In the U S A there is what is called "The Open Forum" In a large hall, filled with people, eminent medical men and women, themselves in active practice, descant upon diseases upon which they are recognised authorities The address is broadcast, and the "hook up" extends to several million hearers "The Open Forum" is organised by the State Medical Society, which is the equivalent of our B M.A.

* * *

A heap of difficulties present themselves in a full consideration of this controversy Cold anonymity creates no real interest in any article on a special subject and "our medical correspondent" may be the sub sub editor with a flair for pseudo medical knowledge or a newly fledged doctor bent on supplementing his—as yet—all too slender fees by turning an (?) honest penny in this way, in either case the title to real knowledge is suspect If we hand over this function to those who have the ability to write and who yet, being retired, cannot be said to be getting an advertisement out of the publication of their names the reader is quick to know that the writer is out of touch with live patients and so is prone to doubt if he is getting "the goods," and we know that his doubts, if not justified to day, will be justified to morrow

* * *

Again, this task cannot be left to a doctor *merely* because he writes well. Was it not of Goldsmith that Garrick said he "wrote like an angel and talked like poor poll"? A doctor may be a good publicist and a poor practitioner Indeed it has been said that in proportion as a medical man is a good publicist he is probably a bad doctor Least of all those to whom this business of health education can be entrusted is the obsessionist And we have such amongst us To one or two of these, "operating" in the past two decades, we no doubt owe the fact in part that the great majority of us have decided to leave the thing alone, lest worse harm befall the public than has befallen it already When "A Chronicler" tells us that "the remedies and adjustments for human defaults, physical and other cannot be standardised for individuals, since many factors having quite different values will be present," he is probably influenced a little by the appalling blunders committed in the name of health education by those who have laid down in the daily press universal rules and prescriptions regardless of *age* sex height, weight complexion *temperament* occupation and a *number* of other considerations There are tears for these things

Yet I cannot somehow think that our American friends are entirely wrong. I felt sure the diabetes specialist was wrong when he talked about acidosis to the general, even without *defining* the word and that this wasn t remedied by the known fact that his reputation was international. But I do feel that there is something that wants doing not by way of "medical advice for individual needs but by way of general knowledge about the human body about diseases and about the principles that underlie both preventive and curative Medicine

* * *

One of my chief reasons for thinking this is that I believe such information if given truly lucidly and attractively would be a valuable *set-off against* the credulity quackery and commercialism with which the public is saddled I would go so far as to say that if this one object were kept well in mind by the writers with complete frankness and with some courage a valuable social service might be rendered. But whether the newspapers would open their columns to matter which exposed the gigantic frauds now practised upon the ignorant public by the vendors of patent medicines patent foods and ' medical gadgets of divers kinds is another question The advertisement manager might well intervene. But we should at least know if the grievance made against us by sections of the lay press that we keep from their readers information and help which it is our duty to give them is genuine and sincere.

As it is, we see a host of new and fictitious diseases being constructed *the basis of all of* which is *none* other *than* the *cleverly concealed fact that* its your money we want Night starvation spring face starch heaviness

Fleet Street history still tells the story of a record coup made by an enterprising daily paper when three letters appearing on three successive days *in* the splash *page*, over names which carried weight *stopped* completely in 24 hours the enormous sale of a patent medicine which did *not* contain what it said it contained and *did* contain something that was not revealed. No one seriously supposed that the main purpose of the paper was to render a philanthropic service Yet this was undoubtedly done Surely the *time* is ripe *for* another coup ? I throw *out the* hint for all whom it may concern.

* * *

Coming back to the matter of the traditions of the profession in respect of advertising the salient point is clear and I hope, ineluctable a doctor must rely for his reputation upon the work he does in his own sphere be it general or consultant not upon mere publicity and the value of this work *must* be judged by his colleagues and by his own patients The sick person and his friends must not be put in such a position that they are influenced to consult him by reading his articles in the lay press or by seeing his photograph there It has been said that it is not possible nowadays *for a doctor to* have prestige without a certain amount of publicity whereas it is possible to have a lot of publicity without much prestige That is true and should be remembered in extenuation of some paragraphs in the lay pres concerning which the doctor is the victim and not the culprit In the *last analysis we are all of us either social or anti-social. The doctor is tempted to be* anti social almost every day of his life He may lower the standard if he likes but if he believes that the present canons of professional ethics are in the public interest he must come into line with them not only passively but by active resistance against attacks made against them

---

PANEL AND CONTRACT PRACTICE

Understudying the Dentist

LAST year Dr X an insurance practitioner in London charged 10s to an insured person on his list who applied for his services late one night on account of bleeding from a tooth socket In July 1936 the London insurance committee ruled that the service rendered fell within the definition of the proper and necessary medical services which the practitioner is required by his terms of service to render The insurance committee therefore decided to deduct the 10s from the practitioner s remuneration and to refund it to the insured person

Dr X appealed against the decision in order to raise the general question of the scope of the terms of service in relation to dental work He contended that dental work was never meant to form part of insurance practitioners duties as covered by the capitation fee He cited the recognised allowance of extra payments for dental anæsthetics administered by insurance practitioners to patients on their lists The Ministry s circulars he believed gave no specific authority for this allowance The inference was that dental services were regarded as in a special category—like attendance at confinements The medical service subcommittee s report said Dr X seemed to make capital out of his admission that the service rendered by him was a medical service but of course any service rendered by a doctor was a medical service the administration of *dental* anæsthetics was a medical service and yet extra payment was allowed *for it* The patient who had suffered from the dental hæmorrhage had written that she would naturally have applied for treatment to her dentist but for the fact that the time was midnight This, said Dr X was an admission that she had merely made a convenience of the panel doctor Responsibility for hæmorrhage *following* dental extractions rested *primarily on the dentist* who performed the *operation.* Medical intervention in such cases might be regarded as an act of courtesy for which the dentist might feel inclined to render the payment or it might be deemed analogous to the now well-established routine adopted in emergency cases occurring on other doctors lists Dr X recalled a recent resolution passed by the London panel committee recommending a solution of the problem on these lines

The Minister of Health took the view that there should have been a formal reference to the local medical committee but invited the observation of the committee on the point In reply the committee relied on Clause 8 (1) of the terms of service defining the treatment which a practitioner is required to give to his patients such treatment comprises all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess Dr X, said the committee, had never contended that his service in arresting the dental hæmorrhage was not medical service or that it involved special skill and experience beyond that of general practitioners as a class The committee referred to the report of referees dated Sept 10th, 1915, which dealt with similar facts The report left no doubt that the arrest of hæmorrhage of the gums occurring seven hours after extraction was a medical service and one within the competence of the practitioner, the suggestion that it was the duty of the dentist to stop the bleeding was rejected as irrelevant, the failure in duty (if any) of one person was no excuse for the failure of another to perform his contract "The bleeding at 11 30 in the night was a matter calling for the medical treatment which the practitioner was bound to give, and his obligations were in no way affected by the origin of the bleeding"

The decision of the Minister on the appeal (which was determined summarily) was as follows The question whether the service rendered by Dr X was within the scope of the obligations under the terms of service was ruled to be a matter to be dealt with, in the first instance, by the local medical committee in accordance with Article 43 of the Medical Benefit Regulations in the circumstances, the findings and recommendation of the medical service subcommittee, and the decision of the insurance committee based on them, were held invalid. Dr X therefore succeeded in his appeal. In conveying this decision, the Minister pointed out that the allowance of the appeal did not imply any decision on the scope of the service rendered by Dr X. He gave no direction as to the costs of the appeal.

The result is inconclusive and unsatisfactory The insurance committee is now referring the matter to the local medical committee under Article 46 of the Medical Benefit Rgeulations of last year, to obtain a decision as to the range of medical service—namely, whether the service rendered by Dr X fell within the scope of his obligations or not Meanwhile the proceedings have at least had the advantage of focusing attention, as Dr X intended, on the relation of dental work to the medical practitioner's capitation fee

CORRESPONDENCE

REST HOUSES FOR RHEUMATOID ARTHRITIS

To the Editor of THE LANCET

SIR,—I have read with great interest the leading article in your last issue entitled "Rheumatoid Arthritis A Move On" It is time for a constructive national policy for the care and cure of those suffering from arthritis I would submit that, if treatment centres are to be set up near the homes of the cases and special hospital provision made, the medical orthopædist should be a member of the organisation This is not primarily for the purpose of dealing with the ordinary physical methods of treatment required, nor even for the prevention and cure of deformities It is in order that methods of physical treatment may be organised which will build up the bodily resistance of the cases, by establishing correct use posturally of the body as a whole Poor posture is almost always present in cases of chronic arthritis

The group of symptoms called "arthritis" can be understood better when we look at them from the viewpoint of the student of "body mechanics," and realise the local and general functional disturbance which habitual bad posture *can produce* Arthritis is not a disease of joints alone, but a widespread disorder of the whole body Whatever the factors at work, the poor posture and lowered tone are parts of a vicious circle which must be broken The atrophic form of arthritis is a degenerative disease much more common in women than in men It occurs between the ages of 20 and 40, and almost always in the slender anatomic type of person There is a profound failure of the body to do its work With these conditions present, infection ultimately takes place The background of inherited anatomic structure, prolonged visceroptosis, and poor posture result in progressive faulty function of the diaphragm, heart, lungs, and the misplaced abdominal viscera The infection comes later when resistance is broken down The longer the imbalance continues, the greater is the damage done

Improvement of the bodily resistance cannot occur without prolonged rest and reconstructive treatment by *skilled medical orthopædic care to* correct the faulty bodily posture, to allow every organ of the body to do its work to full capacity We must strive to obtain perfect and not imperfect use of the body in standing, sitting, walking, breathing, and in lying down Without this part of the work, diet, rest, warmth, relief from strain, and the removal of infection *cannot* be expected to maintain a cure. They only lift a temporary burden

The changes of arthritis can be prevented and checked if taken early and approached with these ætiological points in mind. I would submit that the medical orthopædic care of these cases is an art which is very little understood in this country The problems of disturbed physiology of the organs, viscera, and nervous system within the abdomen do not differ essentially from an internal derangement of such a relatively simple structure as a joint The same orthopædic principles, based upon a knowledge of anatomy and of right and wrong working conditions, apply equally to both. Arthritis is fundamentally an *orthopædic problem* in large measure. Physical resistance and bodily strength can be maintained or restored only by correct use and correct living

Who is not familiar with the case of atrophic arthritis in which the chest is flat, the diaphragmatic excursion is practically absent, and the abdominal organs "dropped"? In some of the cases, so bad is the bodily mechanics, that it is hardly possible to insert a finger at the subcostal angle, and when one does so, it comes down at once upon the spine, so empty are the subdiaphragmatic spaces With the loss of abdominal fat and the loss of the protection normally afforded by the properly positioned organs and viscera to the sympathetic nervous system in this situation, an inhibitory stretching results With the consequent depression of all the vital functions and poor tone, it is essential for successful treatment that the medical orthopædic care of the case should proceed along with the purely medical care Herein lies the main province of the orthopædist, to assist in the establishment of right use of the body wherever and however it may have gone wrong

I am, Sir yours faithfully

W A. COCHRANE

Edinburgh Feb 1st.

To the Editor of THE LANCET

SIR —I read with great interest your last week's leading article on the convalescent treatment of chronic arthritis in adults For some years we have been treating cases of Still's disease at the Children's Heart Hospital (belonging to the Invalid Children's Aid Association) at West Wickham Kent. The progress they have made in open-air country surroundings has been very satisfactory and a great contrast to their lack of improvement whilst in city hospitals. I think that Dr Fortescue Fox's suggestion should receive wide support but those who undertake the supervision of such convalescent homes should realise that more than a few months treatment will be necessary in many cases Moreover as Dr Fox has emphasised in his scheme facilities for physiotherapeutic treatment, skilled massage, and orthopædic measures to prevent contractures occurring will be a necessary part of each establishment

I am Sir yours faithfully

BERNARD SCHLESINGER.

Portland place W Feb 1st

To the Editor of THE LANCET

SIR —In your leading article last week occurs the statement Dr Fox himself attaches value to the use of pure sulphur waters in the treatment (of rheumatoid arthritis) and such waters are not available nearer than Wales Ireland or the north of Scotland Presumably the word pure indicates virtual absence of chlorides sulphates, &c implying that sulphide is the characteristic ion In this case the Harrogate springs such as the Harlow Beck with and Oakdale are as fittingly placed in that category as those in the districts mentioned. Neither by road nor rail can Harrogate be termed remote Although the strongly salinated waters founded Harrogate's reputation the diversity of springs due to the geological complexity of the underlying rocks has given to medical hydrology a great variety of media

I am Sir yours faithfully

DERMATITIS AND MOTOR FUMES

To the Editor of THE LANCET

SIR,—Dr Whitfield's note on dermatitis from motor fumes is of interest and indicates an obscure external cause for some cases of eczema of face and neck In October 1930 I saw a lorry-driver with marked irritation and variable dermatitis of face and neck in which I suspected fumes as a possible cause As his work involved the loading of barley on to his lorry I patch tested him against petrol and barley He gave a strong positive reaction to petrol, a negative reaction being obtained in other control subjects who were tested. I have little doubt that this was the explanation of his dermatitis which has persisted since he has not been able to change his work I shall now try the effect of his driving with an open window in view of Dr Whitfield's suggestion

I am Sir yours faithfully

INFLUENZA AND LEUCOPENIA

To the Editor of THE LANCET

SIR,—The recent research work on the ætiology of influenza and numerous letters and articles lately in the medical press relevant to the symptomatology and treatment of this disease prompt me to call attention to an article published fifteen years ago in your columns (*Lancet* 1922 1 116) by the late Dr F M. Gardner Medwin and myself. Influenza in its present and recent form in this country is far from being the fatal disease which we know that it can at times become it is very different now from the dreadful pandemic of 1918–19 but there can be no assurance that it may not yet again reassume the malignant form. A healthy dislike of anything suggesting commercialism and the pontifical utterances of many of our leading physicians have encouraged a non possumus attitude in regard to treatment We are told to fold our hands to rely on rest in bed warmth and nursing and to avoid any attempt to influence the course of the malady by any method of chemotherapy This is doubtless good advice in regard to the treatment of the vast majority of cases of the present type but I think it is to be regretted if it is to be applied invariably

In 1918 and 1919 working at the 17th General Hospital in Alexandria Gardner Medwin and I came to the conclusion that influenza was due to a filtrable virus; that this caused a leucopenia which was an index of the inhibition of reactionary defence by the body that the state of defencelessness thereby induced laid the host open to attack not only by the primary virus but by various germs—normally harmless but potentially pathogenic—which are commonly to be found in the throat and upper respiratory tract that prognosis depended on the number of circulating polymorphonuclear leucocytes (granulocytes) since the severity of the symptoms bore a direct relationship to the degree of leucopenia and recovery was always preceded and accompanied by a rise in the white blood count and that if one could provoke such a leucocytosis—e g by the injection of such a drug as sodium nucleinate the nucleotides not being known in those days—the disease was dramatically cut short and recovery ensued It is not suggested that the granulocytes per se are necessarily the only defence mechanism though I think that they are an integral part of it; and even then we inclined to the view that they were an index of the capacity of the host as a whole to respond to the infection by the production of antibodies against both virus and secondarily invading bacteria In other words we thought that the body itself could deal with the infection if only we could overcome the curious paralysing effect on its defence forces of the virus They offered the ingenious explanation that the virus had a negative chemotactic effect on the leucocytes and that the nucleinate acted as a chemotactic whistle" to call them out

In the beginning we adopted a system of control by dividing the whole series of cases into two The general treatment was the same in each but only those in alternate beds received the nucleinate After a little while we found such a striking difference in the mortality rate—those who received the nucleinate for the most part recovering and those who did not for the most part dying—that we did not feel justified in continuing to withhold it from the control cases The only criterion was the presence of a leucopenia; naturally in every case repeated blood counts were done to gauge the effect of the treatment We observed two phases of the epidemic *the first* in *the* hot weather from July to October—when such things as "colds" in Egypt are unknown—and the second in the cold weather from the end of November, 1918, onwards It is perhaps of significance that this period was marked by a degree of cold and wet which was most unusual for Egypt In the first phase, the virus was evidently neurotropic, the illness causing fever, severe headache, generalised neuritic pains, and in some cases symptoms resembling an acute encephalitis Lung complications were minimal, the disease was of short duration, although convalescence was marked by depression, and the mortality was practically nil. None of the people who contracted this influenza fell victims during the second phase, in which the onset of the disease was similar but was marked by the early onset of lung complications with an excessive mortality The production of a leucocytosis by sodium nucleinate—the earlier, of course, the better—seemed to have a specific effect in saving life, especially in the heliotrope cases

I should repeat that the drug appeared to have no effect unless a leucopenia was present, and unless it could provoke a leucocytosis It was useless in cases of non influenzal pneumonia where a leucocytosis was already present, and in the few cases under our care where there were, presumably, no leucocytes to call out owing to an aplastic condition of the hæmopoietic system Cases of established leucopenia due to pernicious anæmia or long continued severe malaria, for instance, showed no response Reasoning by analogy I have since tried the drug in a few cases of distemper in dogs and in the very fatal "influenza" of cats The results have been very encouraging, although, of course, I have not controlled these by blood counts and the number of cases treated is quite insufficient to allow of any definite conclusion being drawn from them One *word of warning Not all preparations of sodium* nucleinate provoke a leucocytosis in normal people, it follows that every batch must be tested on a volunteer (we always used ourselves) before reliance can be placed on it

I fully realise that in venturing thus to suggest that the physician treating influenza may possibly be able to do more than supervise the nursing I am laying myself open to that very criticism which has been so unsparingly poured forth in the English medical press of late, reinforced as it has been by all sorts of clichés which may be summed up in the phrase "Dépêchez vous de vous en servir de ce remède pendant qu'il guerit"

I am, Sir, yours faithfully,

Fleet Hants Jan 28th J GRAHAM WILLMORE

INTUBATION FOR PERFORATED GASTRIC ULCER

To the Editor of THE LANCET

SIR,—This method of dealing with perforated gastric ulcer, which was described in your issue of Jan 23rd by Dr Robert Leclercq, is certainly not a recent innovation My colleague, the late Mr W G Richardson of Newcastle on Tyne, practised this method many years ago and wrote a paper dealing with it (*Northumb Durh med J* 1907, p 215) At the time of publication he had carried out this plan in a good many cases and it was so satisfactory that he continued to employ it during the rest of his professional career

The title of his paper was "The Advantages of Temporary Gastrostomy in the Treatment of Ruptured Gastric and Duodenal Ulcer" This title perhaps suggests the formation of an independent gastrostomy, but, as a matter of fact, he actually passed the *catheter into the stomach through* the ruptured ulcer, and he was led to adopt that plan because of the very occasional difficulty of closing a perforation At the same time he was so convinced of the advantages of the catheter in the stomach that he sometimes *adopted* this method even when it would have been possible to close the ulcer by suture

Since my association with Mr Richardson I have occasionally used the method for the same reasons which induced him to originally adopt it But in quite a number of other instances I have made an independent gastrostomy even when it *was possible to* completely and safely close the perforation by suture I have especially used gastrostomy in long standing cases of perforations where there is infection of the upper small intestine area with distension and paresis of the upper coils, and also in cases in which the patient is suffering from dilated stomach as a result of marked pyloric stenosis, but in which it is not considered wise to carry out gastro enterostomy because of the accompanying peritonitis It is also valuable when the stomach is big and flabby

I referred to this matter in a Hunterian lecture which I delivered before the Hunterian Society in January, 1925 (*Lancet*, 1925, 1, 183) At that time I had operated for perforations on 147 occasions and I had employed a temporary gastrostomy 26 times Among these 26 patients the mortality was 30 per cent, which is exceedingly high, but they were all examples of either long standing perforation or of perforations complicated by the conditions which I have previously mentioned. In the series the average number of hours after perforation was no less than 17

I am satisfied that such a gastrostomy is sometimes a very great aid in dealing with these cases It acts as a safety valve The stomach can be irrigated without inconvenience to the patient, distension can be relieved by simply removing the catheter plug, and since overdistension of the stomach is always under control the patient may have the satisfaction of drinking much more freely than would otherwise be advisable

I am, Sir, yours faithfully,

G GREY TURNER.

Hammersmith Hospital L C C Ducane-road W, Feb 1st

APPENDICITIS AND ALARM REACTION

To the Editor of THE LANCET

SIR,—Some of the pathologic anatomical changes described by Dr Hans Selye[1] under the name "alarm reaction" as the result of non specific irritants, raise a strong suspicion of their pure vasomotor character, a possibility which is supported by older and more recent observations, apparently of the same order Amongst the older observations are those by Rossbach[2] and by Aufrecht[3] These demonstrated very clearly the *direct effect of cold on* distant parts of the body in the production of strong vasomotor reactions in trachea and lungs, showing themselves first in spastic anæmia followed by marked congestion, and even fibrinous and leucocytic exudates The gastro intestinal ulcerations, and the appendix lesions more particularly, of this alarm reaction are, as far as one may judge from the meagre anatomic histological details, of similar neurovascular order

---

[1] Acute Phlegmonous Appendicitis produced by Intravenous Administration of Histamine *Lancet* 1936 2 1210

[2] *Berl Klin Wschr* 1882

[3] *Dtsch Arch Klin Med* 1916 119 270

In the gut these ulcerations resemble those multiple forms which appear in uræmia, metallic poisonings (mercury) and in infections These intestinal ulcerations are now generally accepted by pathological anatomists as the result of necroses from blood stasis in paralysed terminal vascular segments (infarcts)

Space does not permit further expositions but those interested may be referred to G Ricker[4] and E Kaufmann[5] As regards appendicitis on such a neurovascular basis Ricker's article on epityphlitis[6] is noteworthy He puts first in the appendix attack an abnormal irritation of its nervous system and also that infection arises secondarily on the basis of the exudative and necrotic primary neurovascular changes He regards the appendix lesion as the akron of a general splanchnic increased irritability A review of this matter may also be found in the section on appendicitis by Christeller and Mayer in the Henke Lubarsch Handbuch (vol. 104 p 530)

Finally an experimental study by E Reinhardt and Ricker[7] entitled a Critique of the Doctrine of Cellular and Humoral Stimulation of the Cutaneous Circulation devotes some attention to the histamine factor (the fashionable substance which at present seems to be brought into relation to all the ills the human kind may be subject to) and points out the scientific and epistemological weakness of such a purely biochemic explanation of living events

Perhaps your readers will be interested in obtaining these additional references

A BILL TO SECURE MEDICAL PRIVILEGE

To the Editor of THE LANCET

SIR,—Having won an early place in the Ballot for Bills, I have been allotted a time next Friday Feb 5th to introduce a Bill and I am taking this opportunity of presenting a measure to secure privilege under certain conditions from disclosure of communications made to medical practitioners by their patients under the seal of confidence I append the text of the Bill as it is printed and as I propose to present it I may say that some of the clauses especially those relating to the prevention of crime or fraud have been drafted for me by Lord Atkin who has publicly stated his opinion that some measure of professional protection should be afforded to medical practitioners as it is to e g solicitors

In November 1927 I obtained under the Ten Minutes Rule a first reading for a Bill in essentially the same terms as my present Bill with the exception that in the earlier Bill I was advised by legal members in the House to limit the operation of the Bill to cases of venereal disease that limitation being suggested by the fact that patients attending venereal clinics under the ægis of the Ministry of Health are assured upon coming to the clinics by leaflet and personal promises that their confidences will be respected This protection was found to be illusory some short time before I brought forward the early Bill and several legal members of the House assured me at the time that they agreed with the Bill as it then stood indeed a number of eminent lawyers[8] gave the support of their names on the back of my Bill I did not proceed further with the early Bill as inquiries convinced me that even if the Bill passed the Commons the Lords, led by Lord Birkenhead would reject it. I believe there will be less opposition now from legal members of both Houses and this belief as well as another consideration have weighed with me in making my new Bill of wider application The drawback of limiting the Bill to venereal diseases is obvious, in that any person pleading its protection in a court of law would by implication be liable to the imputation that he was suffering from venereal disease

At the ninth International Congress of Dermatology held in Budapest in 1935 when I was president of one of the six committees appointed by the congress the purpose of my committee being the consideration of medical problems affecting public interests I chose as one of the subjects of my committee the discussion of the degree of protection awarded to the professional secret in those countries represented upon the committee which included members from nearly every State in Europe and from the United States It became obvious that the protection given to the professional secret abroad was much more efficient than in our own courts, and no miscarriage of justice from this protection was recorded by the various speakers That widely distributed experience should dispel any fears entertained by the lawyers in our country that the protection afforded by my Bill safeguarded as it is from improper use would be followed by untoward results.

I am Sir yours faithfully

House of Commons Feb 1st L GRAHAM LITTLE.

ENCLOSURE

Medical Practitioners
Communications Privilege 5th February 1937

A BILL

TO

Provide that certain communications between medical practitioners and their patients shall be privileged from disclosure in evidence

BE it enacted by the King's Most Excellent Majesty by and with the advice and consent of the Lords Spiritual and Temporal and Commons, in this present Parliament assembled and by the authority of the same as follows —

Privilege from disclosure in courts of law

1 Any information obtained by a duly registered medical practitioner in the course of treatment of any patient shall be regarded as confidential and shall be privileged from disclosure in a court of law :

Provided that the information obtained shall have been obtained for the purpose of a cure or assisting in a cure of a person so treated :

And provided also that this privilege (*a*) shall not extend to any communication made with the object of committing or aiding in committing any fraud or crime and (*b*) shall not extend to any disclosure in any court of law in any case founded on a criminal charge or charge of fraud against such patient

Definition.

2 For the purpose of this Act duly registered medical practitioner shall mean a person whose name is on the Medical Register

Short title

3 This Act may be cited as the Medical Practitioners Communications Privilege Act 1937

DYSOSTOSIS CRANIOFACIALIS

To the Editor of THE LANCET

SIR,—A case of craniofacial dysostosis is reported by Prof. A J Ballantyne in the January issue of the *Proceedings of the Royal Society of Medicine*. He suggests that the cause of this condition is quite unknown and although this is true I should like to draw attention to a theory which I published in the *Journal of Neurology and Psychopathology* (June, 1934). This theory was that the synostosis which is so evident and which is the apparent cause of the distortion is due to some condition which prevents the brain growing normally, and which inhibits various areas. If I may quote from my paper

> "It has been admitted since the failure of operative measures in microcephaly that the growth of the skull is dependent on the growth of the brain. In microcephaly the brain does not grow to the usual size and the skull shapes itself to conform to it. Again in porencephaly the skull is often flattened over the undeveloped half of the brain. It will therefore appear probable that any deformity of the skull is the result of cerebral disease and not of disease of the bones or sutures. For some unknown reason the fœtal brain does not develop at the normal rate and in normal directions. Possibly the brain even stops growing for a time. This uneven development allows the sutures to fuse where they are in contact"

This theory explains all these conditions of cranial deformity. In my paper I suggested that whether oxycephaly, hypertelorism, craniofacial dysostosis trigonocephaly, or any other member of the group is produced will depend on which part of the brain is sluggish in its growth. If it is mainly the frontal lobes which are affected, so that the coronal sutures are allowed to fuse, the brain will find itself forced to enlarge the skull upwards, producing oxycephaly. If the parietal lobes are at fault scaphocephaly is produced. Hypertelorism and cranio facial dysostosis appear dependent on disproportionate growth of the occipital, and possibly other lobes (this may explain the abrupt occiput in hypertelorism).

I agree that a general title is necessary but I would suggest that of cephalic dysostosis should be used (instead of the one suggested by Prof Ballantyne, which has so far been limited to Crouzon's disease).

I am, Sir, yours faithfully,

Harley street W, Jan 26th CLIFFORD ALLEN

RADIOGRAM AND RADIOGRAPH

To the Editor of THE LANCET

SIR,—Permit me to contribute the following additional observations in support of the noun *radiograph*.

Prof Oliver Lodge probably coined this word, for it was the name he gave to the photographs taken by the new Roentgen rays which he used to illustrate his paper at Liverpool on March 26th, 1896, and it is recorded in the *British Medical Journal* of April 4th, 1896. This association many of us would like to preserve for obvious reasons. I cannot find as early a reference to *radiogram*.

In your comment on my quoting *photograph* as precedent you state that this is really an unlucky exception to a convenient rule. There is more in my suggestion than similarity of the objects and their processing. Prof. Arthur Schuster, making the earliest British reference to Roentgen's discovery (*British Medical Journal*, Jan 18th, 1896) called the radiographs which Roentgen had sent him *photographs*, and in the same journal (Jan 25th) will be seen a radiograph of the hand with a note "It is a photograph of his own hand taken by means of the new radiation discovered by Professor Roentgen."

The terms *Roentgen photograph* and *X ray photograph* are still to day in use. The nouns *skiogram* and *shadograph* appeared in the *British Medical Journal* for Feb 22nd, 1896, and Sidney Rowland used the nouns *skiagram* and *skiagraph* in his serial articles there during March and April, 1896, but the term *skiascopy* was applied to the shadow test in refraction before Roentgen's discovery and to wrest it from its original setting does not appear praiseworthy.

Your comment, "Our preference for *radiogram* is based on the analogy of *telegraph* and *telegram* ... *telegram* was devised to signify what was written by the telegraph" Surely this lends support to the use of *radiogram* for the wireless message? But there are Greek scholars (see *British Journal of Radiology*, March, 1927, p 115) who say that "telegram is the vilest abomination ever popularised. It is an impossible compound. The true Greek form would be Telegraphene. A telegraph would be better ... Skiagram is an impossible compound violating every rule of Greek formations"

I have been at some pains to go through the contributions to the *British Journal of Radiology* for the past six years and the following is an analysis of the terms employed, each contribution having but one score —

Radiograph	181	X rays	6
Radiogram	56	X ray photograph	3
Skiagram	30	X ray pictures	6
Skiagraph	3		

One may say that the term *radiograph* is used exclusively for the photograph taken by X rays, and its continued use by a large section of the profession and the public is not likely to lead to any confusion, whereas, whether we like it or not, the term *radiogram* is now the household word for a radiogramophone and not likely to be supplanted.

I am, Sir, yours faithfully,

Birmingham 15 Feb 1st JAMES F BRAILSFORD

To the Editor of THE LANCET

SIR,—*Radiogram* and *radiograph* are both ill bred and bastard words, and it is difficult to know which to legitimise by official adoption as the term for an X ray picture. The mixed Latin and Greek parentage is avoided in the terms *skiagram* and *skiagraph*, but they are somewhat archaic in sound, as is pointed out in "Radiogrammarian's" letter (a pseudonym, be it noted, also with a bar sinister!), and strictly they mean *shadow picture*, the negative of *photograph* or *light picture*. It seems that although of blue blood, they are in the category of lost causes, and that the battle will rage round the first two words.

In the word *radiograph* the suffix *graph* may be regarded by some as derived from the Greek verb "graphein" to write, in which case *the* word becomes a verb, denoting the act of taking an X ray picture, a sense in which it is used by the majority of radiologists. On the other hand those who use *radiograph* as a substantive may claim that its suffix is then derived from the rare Greek noun "*graphē*," meaning a picture or painting. The objection to this is that "*graphē*" is never used in Greek in a compound word. An alternative derivation of *graph* in the substantive might be "*grapheia*," the Greek abstract noun, but this would be properly translated *graphy*.

Those who, like myself, use *radiogram* as the noun, are on safe ground in the respect that "*gramma*" (a letter, or thing written) is often employed in com pound words (cf. anagram, diagram epigram), and the objection to it lies only in its literal meaning —i.e a thing written by a ray In defence of this inaccuracy may I suggest that the important element in an X ray picture is not its pictorial effect or *graphē* ' but its message or *gramma* (pace those who do not read radiologists reports) and that the secondary meaning justifies its adoption as a noun in preference to *radiograph*.

Other advantages of *radiogram* are as Radio grammarian has pointed out euphonic and practical. It is somehow tidier to have different words for the noun and the verb Again do the advocates of *radiograph* propose to talk of *cholecystograph* or *pyelograph*? I confess they come awkwardly to the tongue

The piracy of the wireless and gramophone interests are to my mind a further incentive to hold fast to the word coined first in radiology As for *röntgenogram* or *röntgenograph* the sound of them is enough! I would almost as soon use *augeograph* or *radiopict* both of which at least have parents of the same stock.

Finally is *X ray* really spelt without a hyphen?

I am Sir yours faithfully

NASAL SINUSITIS IN CHILDHOOD

To the Editor of THE LANCET

SIR —There is no doubt that chronic antral infection is often overlooked both in children and adults and there is not necessarily any fluid to be found in the infected antrum. In fact the dry antrum with the infected membrane is a greater cause of trouble than where there is fluid in it. Where a few antrum punctures and wash outs do not cure the infection an intranasal opening should be made so that daily lavage of the cavity can be done. If the antrum recovers frequently the other cells do also

I am Sir yours faithfully

C HAMBLEN THOMAS

Harley-street W Jan 30th

WHEN WAS JOHN HUNTER BORN?

To the Editor of THE LANCET

SIR,—The approaching anniversary of John Hunter s birth recalls the various dates that have been given by various people for that event. These number at least four

(1) July 14th 1 8 This is the date given by Sir Everard Home in his memoir of Hunter s Life prefaced to Hunter s treatise on the blood inflammation and gun shot wounds. In a copy of this work in the Royal College of Surgeons library is a marginal correction to February in William Clift s beautiful handwriting

I believe but have not the reference by me that Sir E Home himself subsequently corrected the error but without so far as I know explaining how he came to make the mistake It is surprising that so gross an error should have been made by one who was Hunter s resident pupil assistant locum tenens successor brother in law and executor under his will

(2) Feb 7th 1 28 This is a written entry on the fly leaf of a small bible presented to the Royal College of Surgeons by the late Miss Helen Baillie The entry records the marriage of Hunter s parents the years (and in some instances the dates) of the births and deaths of all their children John s death alone is wanting

(3) Feb 13th 1728 In the appendix to Dr Adams s memoir a letter to the author from the minister of East Kilbride is quoted It says that this date is that given in the baptismal register of the parish of East Kilbride and that he was baptised on March 30th It adds that Hunter s mother s name is entered as—Paul

Paul was the lady s unmarried surname Her Christian name was Agnes. It is plain that the informant did not know her Christian name and therefore was not Hunter s father

(4) Feb 14th 1728 Ottley in his Life prefaced to Palmer s edition of Hunter s works says that Hunter himself used to date his birth on this day which consequently is that on which his anniversary is celebrated at the College of Surgeons.

Hunter's evidence can only be hearsay despite the fact that he was a principal party and present on the occasion On the whole it seems most probable that he was born on the night of Feb 13th–14th 1728 about midnight and that the exact time was not observed by any of those present at the birth.

I am Sir yours faithfully

Southampton-row London, W C. Feb 1st

B M.A AND T U C

SOME time ago Sir Walter Citrine secretary of the Trades Union Congress approached the council of the British Medical Association with a proposal for a working link between the trade-union movement and the medical profession and suggesting a standing joint committee to deal with subjects on which coöperation would be advisable The settlement of the dispute at Llanelly paved the way for some arrangement of this kind and the appointment of a joint committee has now been announced as follows

For the B.M A Sir E K Le Fleming (chairman of council) Sir Henry Brackenbury Dr H G Dain Prof R M F Picken Dr J W Bone Dr H W Pooler and Dr G C Anderson (medical secretary)

For the T U C Mr Ernest Bevin, Sir Walter Citrine Mr A Hayday M.P (chairman of the Social Insurance Committee) Mr W Kean (chairman of the Workmen s Compensation and Factories Committee) Dr A Welply and Dr F A Gregg (Medical Practitioners Union) and Dr H B Morgan (medical adviser to the T U C)

This joint committee will meet alternately at the house of the B M.A and the T U C the chairman to be drawn alternately from either side. The joint secretaries of the committee are Dr Charles Hill for the B.M.A and Mr J L. Smyth for the T U C

ROYAL EYE HOSPITAL, SOUTHWARK.—Sir John Simon was the principal guest at the Coronation dinner held in aid of this hospital on Jan 22nd when subscriptions amounting to nearly £2000 were received The hospital in 70 years has dealt with over a million patients and is the only London eye hospital south of the Thames though there are four on the north bank Over 000 cases of industrial eye injury were treated last year

NEUROSURGERY AT EDINBURGH ROYAL INFIRMARY.—At a recent meeting of the court of contributors to the Royal Infirmary of Edinburgh reference was made to the accommodation of fee paying patients in the neurosurgical ward The managers of the infirmary have not previously made any provision for fee-paying patients; but it was pointed out at the meeting that the circumstances are peculiar in that neurological surgeons require a special team of trained assistants and nurses and it is impracticable for the neurological surgeon to have one such team in the hospital and another outside in a nursing home Ward 20 is in the process of being reconstructed as a ward for neurosurgical patients who are at present scattered throughout the hospital

NEW YEAR HONOURS

THE delayed list issued on Monday contains the names of the following members of the medical and dental professions —

G C S I

H H the Maharaja of Gondal, G C I E, M.D, F R C P E, F R S E, LL D

K C V O

John Fraser, M C, F R C S E
Regius professor of clinical surgery in the University of Edinburgh

Knights Bachelor

Joseph Arthur Arkwright, F R C.P, F R S
Member of the Agricultural Research Council

John Charles Grant Ledingham, C M G, D Sc, F R C P, F R S
Director of the Lister Institute professor of bacteriology in the University of London

Ernest Kaye Le Fleming, M D
Chairman of the council of the British Medical Association

John Henry Morris Jones, M C, L R C P, J P
M P for Denbigh, Lord Commissioner of H M Treasury

C B (Military)

Major General T S Coates, O B E, M B, K H P
Deputy director of medical services, Aldershot Command

Major General A W M. Harvey, M B, K H S, I M S
Deputy director of medical services, Northern Command, India

C M G

William Henry Kauntze, M B E, M D
Director of medical services, Uganda Protectorate

C I E

Lieut Colonel R E Flowerdew, M.B, I M S
Inspector general of prisons Bengal

Graham Colville Ramsay, O B E, M.D
Deputy director of the Ross Institute (London School of Hygiene and Tropical Medicine)

C B E (Military)

Surgeon Captain W J Carr, M.R C S
Director of medical services, Royal Australian Navy

Surgeon Captain (D) Edward Ernest Fletcher, O B E, L D S, R N

C B E (Civil)

Percival Alfred Dingle, M R C S
Principal medical officer, North Borneo

O B.E (Military)

Lieut. Colonel G B Hanna, L R C P, I M.S
Officer commanding the Indian Military Hospital, Quetta, India

O B E (Civil)

George Moncrieff Barron, F R A C S
Member of the council of the New South Wales branch of the British Medical Association

Sydney Letts Dawkins, M.B
Medical officer, South Australian Railways

Lieut W S Empey, M.B, I M.S
Recently leader of the British Ambulance Unit No 1 in Ethiopia

Bernard Hart, L M S S.A
Consulting radiologist, Doncaster Royal Infirmary

Victor William Tighe McGusty, M B
Secretary for Indian affairs and inspecting medical officer, Fiji

William Egbert Thompson, M B
Surgeon specialist, Palestine

M B E (Civil)

Manikkam Durairaj David, F R C S E
Third surgeon, General Hospital, Rangoon, police surgeon, Rangoon

Kaisar-i-Hind Medal (Bar)

Louisa Helena Hart, M.D
Medical missionary, Chittoor district, Madras

Kaisar-i-Hind Medal

Lieut Colonel G M. Millar, O B E, M B, I M.S (retd.)
Director of medical services, Jammu and Kashmir State

OBITUARY

HENRY ALEXANDER OSBORN D.M Oxon

As we announced last week Dr Osborn died on Jan. 23rd from a hæmic infection contracted at a post-mortem examination He was pathologist at the Mill road Infirmary and other Liverpool hospitals

Graduating in arts at Natal University College in 1914 Osborn was awarded a Rhodes scholarship War service in East Africa intervened however until he was invalided out of the Army in 1917 with malaria On his recovery he proceeded to New College Oxford and in 1919 went on to King's College Hospital with a scholarship in pathology He qualified in 1921 graduated at Oxford in 1922 and took the D.P H During 1923 and 1924 he held a pathological appointment at King's College Hospital and from 1924 to 1932 he was pathologist in the Laboratories of Pathology and Public Health in Harley-street. During this period he became pathologist to King Edward Memorial Hospital, Ealing and consulting pathologist to Wembley Hospital. In 1932 he was appointed to the newly created post of pathologist to the southern group of municipal hospitals in Liverpool—Mill road Infirmary Smithdown road Hospital and Alder Hey Children's Hospital—with a total of 3000 hospital beds

He took up the task at a time of rapid development of these hospitals, shortly after they were taken over from the old guardians by the municipality It needed energy insight and powers of organisation for both clinical and pathological work was increasing at almost breakneck speed. Indeed, writes a medical friend those of us who were his clinical colleagues look back upon the past five years and wonder how he was able to encompass so much. For the routine clinical pathology of the hospitals was so smoothly and adequately done that it was not until after his death that we became fully aware of just how much personal attention he gave to it He had succeeded so well that we almost came to take his accomplishment for granted Moreover he found time and energy to carry out research on problems in the wards which forced themselves on the attention of an alert mind Troublesome outbreaks of pemphigus in the maternity department led to work on neonatal dermatitis for which he was awarded the D.M Oxon The admission of large numbers of patients suffering from pneumonia stimulated him to an intensive study of the disease in collaboration with clinicians and he was especially fascinated by what he used to term the ecological factors in prognosis—the importance of the soil and especially of undernutrition. Certain types of neonatal death also aroused his thoughtful curiosity and much occupied his mind in more recent months

Osborn was an ideal clinical pathologist spending his time between wards laboratory and post mortem room integrating pathology with clinical work to the advantage of patients and colleagues alike He was always ready and indeed eager for consultation at the bedside on a difficult or interesting case and he himself in turn was anxious always to have the clinician present at the many autopsies which he performed for a proper and equal interchange of facts and ideas He was a strong quiet and unruffled personality his accuracy of mind and attention to detail were qualities therefore which served him well, yet never got out of proportion. He talked slowly and deliberately he would listen in silence with a tolerant smile to intervene at last with some direct critical or thoughtful remark which was all the more effective for being so quietly uttered. There was no cynicism about him; he was kind practical and ready to say honestly and directly what he had to say

Among the memories of our collaboration in hospital there are two which recall Osborn to me as man and friend—the days when in the hospital common room he sat relaxing over a cup of tea puffing at his pipe, and discussing with his colleagues things medical or otherwise with flashes of an almost pawky humour; and the enthusiasm with which even in his laboratory at Liverpool he tried to initiate me into the joys of surf bathing in one of his beloved Cornwall coves

RESEARCH IN DISEASES OF THE BLOOD.—The trustees of the Lady Tata memorial fund invite applications for grants and scholarships for research in diseases of the blood with special reference to leukæmia in the academic year beginning on Oct 1st Grants of variable amount are made for research expenses or to provide scientific assistants to senior workers Scholarships are awarded as personal remuneration and they ordinarily have the value of £400 per annum for whole time research with proportionate adjustment for work on a part time basis where this is approved The grants and scholarships are open to workers of any nationality Applications must be submitted before March 31st and the awards will be made by the trustees in June Further particulars and forms of application may be obtained by writing to the secretary of the scientific advisory committee 12B Bedford Court mansions London W C 1

PARLIAMENTARY INTELLIGENCE

FACTORIES BILL

In the House of Commons on Friday, Jan 29th, Sir **John Simon**, Home Secretary, introduced the Factories Bill, the purpose of which is to consolidate with amendments the Factory and Workshop Acts, 1901 to 1929, and other enactments relating to factories The Bill, which was read a first time, is not only a consolidating measure, it is a revising measure which will bring the provisions of the Factory Acts up to date The main changes proposed are as follows —

The various distinctions which exist in the present law between factories and workshops and between textile and non-textile factories are abolished, and only one term "factories" is employed

Part I, which deals with general provisions as to health, strengthens existing provisions and introduces new proposals The requirements as to cleanliness are made more precise The amount of cubic space required per person is increased from 250 cubic feet to 400 cubic feet, but in existing workrooms the old standard will continue to apply for five years and longer if effective mechanical ventilation is provided A reasonable temperature in all workrooms and a special standard of temperature for light sedentary work prescribed by the Secretary of State are to be maintained, and the Secretary of State will also have power to prohibit the use of unsuitable methods of heating Important new proposals are those for securing sufficient and suitable lighting and for medical supervision of the workers in certain circumstances—e g, in outbreaks of disease

In Part II the provisions of the existing law have been largely re cast New proposals provide for the adoption of various safety devices or arrangements, and impose duties on manufacturers in regard to the construction of new machines Precautions are required in the case of cranes, chains, steam receivers and containers, compressed air receivers, processes involving risk of explosion from dust or fumes, and various other matters Specific requirements are laid down with regard to hoists and lifts The provisions in regard to means of escape in case of fire, for giving warning and for familiarising employees with the routine to be followed, are considerably extended so as to cover all factories in which more than 20 persons are employed, or where explosive or highly inflammable materials are stored or used. Part III deals with general provisions as to welfare, especially drinking water, washing facilities, and accommodation for clothing and facilities for sitting for female workers Part IV contains important new proposals in regard to health, safety, and welfare these concern chiefly the removal of dust, the control of underground workrooms, and the lifting of excessive weights, giving power to make regulations prescribing maximum weights for young persons and men and women Part V reproduces substantially the existing law relating to the notification and investigation of industrial accidents and diseases Part VI deals with the hours of employment of women and young persons At present women and young persons may work in any week up to a maximum of 60 hours in non-textile (55½ in textile) works exclusive of intervals for meals and women may do a limited amount of overtime in certain trades Under this Bill working hours shall not exceed 48 weekly and 9 daily, exclusive of intervals for meals, an aggregate of 100 hours overtime in the year will be allowed for women and young persons over 16, but not more than 6 hours in any week or during more than 30 weeks in the year In trades subject to seasonal or other pressure however, women may be allowed to work 150 hours overtime and the other overtime requirements may also be released "in proper cases' Young persons under 16 will not be allowed to work overtime, and provision is also made for reducing the amount of overtime for those over 16 in any process in which overtime employment is shown to be prejudicial to their health. The same Part also provides for certain exceptions to meet certain special cases

Part VII following the existing Act applies certain provisions of the Act to docks, wharves, quays, and warehouses, it also applies certain provisions to certain processes carried on in ships in a harbour or wet dock which are not at present under the Act, to building operations which are only partly within the Act and to works of engineering construction which now come within the scope of the Act for the first time Parts VIII and IX re-enact the existing provisions in regard to homework and the supply of particulars to piece workers Part X continues with modifications a number of existing miscellaneous provisions, but contains one new provision imposing specific obligations on employed persons requiring them to use the appliances provided for their health or safety and not wilfully or without reasonable cause to do anything likely to endanger themselves or others Part XI contains the administrative provisions relating to the appointment, powers and duties of inspectors and the appointment and duties of examining surgeons (the new name for the certifying surgeon) Part XII re-enacts with modifications the provisions with regard to offences and penalties and legal proceedings Parts XIII and XIV deal with the application of the Act and general interpretation, and the definition of "factory"

It is proposed that the Bill shall come into force on July 1st, 1938, but the Secretary of State is given power to postpone, up to Jan. 1st, 1940, the operation of any particular provision in Part II This would enable special treatment to be given if necessary to any depressed industry which might find it specially difficult to comply with the provisions in question.

MATERNITY SERVICES IN SCOTLAND

In the House of Commons on Jan 28th Mr **Elliot**, Secretary of State for Scotland, moved the second reading of the Maternity Services (Scotland) Bill. In 1935, he said, a report was issued on maternal morbidity and mortality in Scotland by a specially appointed and highly competent technical subcommittee of the Advisory Committee of the Department of Health for Scotland, who were convinced of the urgent need for improvement in the standard of midwifery in Scotland This Bill closely followed the recommendations of this report Its object was to improve the standard of domiciliary midwifery by securing adequate nursing and medical services for women confined in their own homes A death rate of six mothers for every 1000 children born in Scotland indicated a degree of ill health which could not properly be measured, and some of these lives could be saved and much ill-health prevented by properly coördinated arrangements for attending to the health of women before, during, and after confinement in their own homes The Bill differed from the one in England because of the different conditions in Scotland where the doctor played a larger part and the midwife a correspondingly smaller part in the confinement Every expectant mother confined in her own home would be entitled to the services not only of a midwife but also of a doctor and if necessary an obstetrician of recognised standing These would work together as a team under the general administration and guidance of the medical officer of health Since the Scottish practice was for the confinement to be attended by a doctor it was hoped that with the arrangements of the midwife service and the advice of highly qualified specialists at call the doctor would not be required to go beyond minor assistance in the confinement, which was a natural event which he should supervise and guide if necessary but in which the patient was certainly going to play by far the major part

ORGANISATION AND FINANCE

The arrangements that the local authorities would require to make for providing this service Mr Elliot went on would be subject to the approval of the Department of Health but there would of course be some elasticity because such areas as the Highlands and Islands had difficulties in communications which would have to be taken into account It would be open to the local authorities to negotiate with the voluntary associations that employed midwives to arrange directly with those engaged on private work or themselves to establish a salaried service Before submitting the proposals to the Department, however they were required to consult the local voluntary associations and any organisation that had a right to speak for the midwives It was inevitable that when the scheme came into full operation the handy woman would disappear He thought the number of midwives in practice would be reduced by the provisions for compensation on retirement Moreover the midwives would be paid either by the local authorities who engaged them or by their own associations and would no longer have the not uncommon experience of rendering services without fee midwives had thus brighter prospects of a reasonable livelihood than they had had before If a midwife gave up a certificate within three years after the Bill had been passed she would receive as a compensation three years average income If others practised after they had really become unfit they could be called upon to surrender their certificate with the right of appeal to the Department and they would receive five times their average yearly income for the previous three years

The local authorities would be free to select their own methods for securing the medical services so long as these were adequate In some areas the arrangement would be with all the local medical practitioners willing to undertake the service In others the antenatal and postnatal examinations might be carried out at the authorities clinics and arrangements might be made with all the practitioners, or with a limited number the doctor attending being advised of the results of the examinations The service under the Bill was not compulsory but it was expected to be taken advantage of generally

Fees would be graded according to the patient s means and none would be charged to necessitous mothers For insured women the wives of insured men and women in a similar economic position it was hoped that local authorities would be able to provide a complete range of services at home at a fee not much, if at all higher than was at present payable for the services of a midwife alone Women could thus authorise payment to the local authority out of their maternity benefit Payment of practitioners would be in accordance with scales fixed after consultation with the appropriate doctors organisations When the new services were in full operation the additional expenditure after taking into account the fees recovered might reach £120 000 per annum The Bill proposed a grant equivalent approximately to half the total additional expenditure entailed on the local authorities but scaled in proportion to the need of the area He hoped that the proposal he made would seem reasonable to the local authorities He would be prepared to move an amendment providing that the Bill should not come into operation until May 16th which was the day after the new block grants had begun to run The local authorities would also receive Exchequer help to the extent of half their liability for compensating midwives who retired during the three years after the Bill took effect The universities and teaching institutions were concerned about the facilities available for the training of medical students and midwives but provision was included in the Bill that the local authorities and the Department in exercising their functions would have to maintain the facilities for teaching

MEMBERS COMMENTS

Mr JOHNSTON said that Mr Elliot had not explained why the maternal mortality rate in Scotland was 15 per cent worse than that in England nor why in a model area in London instead of a death rate of 6 per 1000 as in Scotland it had been reduced to 0 08 Nevertheless the Labour Opposition welcomed this measure for it was laying the foundations of a new municipal service in midwifery He was prepared however to have not only municipal midwives but also a complete medical service with doctors and midwives in the employment of the local authority Unless some provision was made for home helps women were not likely to accept readily the offer to go into lying in hospitals He asked what provision was to be made for seeing that women were given the nutrition necessary to a mother in child bearing

Sir ARCHIBALD SINCLAIR asked the Secretary of State for Scotland to explain why this scheme was going to cost so much less than that outlined in the report of the Committee on Scottish Health Services the total cost of which was to be £310 000 He suggested that if mothers were subjected to pressure from the local authorities in the payment of their maternity benefit they would be reluctant to avail themselves of the provisions of the Bill It might be wise if only half of the benefit could be transferred to the local authority if the mother authorised that to be done The Highlands and Islands attached very great importance to the recommendation of the Committee on Scottish Health Services that a special supplementary additional grant of £50 000 a year should be made available for the improvement of local authority health services in those areas Unless some such provision was made or unless the new formula for the block grant turned out to be fully as generous as Mr Elliot indicated he was afraid that this Bill would remain a dead letter in the Highland counties.

Mr GRAHAM KERR said he had been assured that unless the Bill was amended in one particular respect it would bring about actual deterioration in the domiciliary midwifery of Scotland For all midwifery cases to be treated in hospital was not yet a matter of practical politics and there was no convincing evidence that it would be an advantage in the present state of knowledge The overwhelming majority of cases to-day were attended at home and it seemed to him as a biologist that no more difficult task faced society than the improvement of domiciliary midwifery to the very highest level To ensure the most efficient training possible in midwifery for the midwife on the one hand and the medical practitioner on the other transcended all else in importance He had had representations from the Scottish universities and from the great maternity hospitals in Scotland not only that the present Bill failed to ensure this, but that the omission would in the long run defeat the whole object of the Bill that it might in its present form wreck the outdoor or domiciliary service of the hospital which is absolutely essential for the training of students and midwives ; and that the number of properly qualified midwives would inevitably decrease or alternatively the standard of their training would be bound to suffer He hoped that the Government would add a clause that in every area where there is a recognised medical school the local authority should ensure that adequate facilities are made available for the practical domiciliary instruction in midwifery of any person undergoing training with a view to becoming a duly qualified medical practitioner or a certified midwife

Mr LEONARD suggested that since many general practitioners did not like to indulge in this work a panel of practitioners who had given special attention to the subject should be consulted He also asked that the same restrictions should be placed on all unqualified attendants whether in maternity homes or in private —Mr ALLAN CHAPMAN said that it was clear that extern training was at least as important as intern training in view of the main object of the Bill He desired to see mothers protected by requiring a certificated midwife always to be present when a student was handling a case, no exceptions being made

THE MEDICAL PROFESSION'S VIEW

Sir **Ernest Graham-Little** said there was a very considerable danger in regarding this measure as a real contribution to solving a problem that was undoubtedly distressing and disturbing the medical profession more than any other Any progress to be made would be through the antenatal period, but most of the provisions of this Bill dealt with intranatal measures, which were too late, all the valuable time having been lost The nutrition of the expectant mother was undoubtedly one of the most important helps to a successful confinement He instanced the maternal mortality in the Island of Lewis which was less than that in Paddington, the suggested reasons being the very small community there and the excellent fresh diet Other dangers that only a medical man could discover during the antenatal period were the physical disabilities sometimes requiring Cæsarean section, cardiac pulmonary disease such as tuberculosis, and the most important of all, venereal disease Sir Ernest supported the plea for more maternity beds, for he said the mortality in well-conducted maternity homes had been very much less than in confinements in the best circumstances at the homes of patients Valuable experiments could only be made under very skilled observation, and at Queen Charlotte's Hospital, for example, a new drug had been tried for sepsis with the result that the mortality had decreased from 22 per cent to 2 per cent Another point was that in the Bill the general medical practitioner was rather left out of the scheme The colleges and universities, after the General Medical Council had sent out a circular pointing out the enormous importance of students obtaining more practical skill in London and elsewhere, had made some great changes in the medical curriculum to meet this need If the part played by the general practitioners was curtailed, it would decrease the urge for improving their education The report of the Committee on Maternal Morbidity and Mortality in Scotland, which he could not commend too highly, indicated certain dangers due to inexperience, of which an important example was a relatively ill-equipped midwife offering to do too much, and nothing was more disastrous at a confinement Antenatal care lessened the need to interfere, for it forestalled danger He would rather spend far more money upon these preparatory measures than on the actual operation of delivery itself, which should be, but very often was not, a really normal physical process It was from the point of view of giving a false idea of security that he thought this Bill would be somewhat of a disappointment to the medical profession

THE GOVERNMENT'S REPLY

After further debate Mr T M **Cooper**, Lord Advocate, replying for the Government, said that the Bill was not concerned with institutional treatment, because that was covered by other measures The authorities were blind neither to the necessity of pursuing the attack on the problem by means of institutional treatment, nor to the advantages to be secured from better nutrition for pregnant and nursing women The present Bill's limited purpose was to provide adequate domiciliary midwifery service Accounting for the discrepancy between the estimated expenditure of £120,000 per annum and the £310,000 in the report of the Committee on *Scottish Health Services*, he said the latter figure included a considerable sum for expenditure that was not included under this Bill, while the £120,000 did not take into account the payments which would be made for the services rendered If it was thought that the Bill could not secure adequate facilities for teaching midwifery the Secretary of State for Scotland and himself would be happy to examine any other formula which would achieve that object The continued supply of competent midwives and doctors was an integral part of the scheme, and they must so adapt their legislation and administration as to enable this to be done On the proposal to exempt from penalty various categories of persons, he said there was all the difference in the world between unqualified interference in a private house, where a great deal of mischief could be done, and unqualified assistance in an institution under the supervision of qualified medical practitioners The first of the four heads, he concluded, for which provision had to be made in the schemes of local authorities was medical examination and treatment during pregnancy as distinct from childbirth This was certainly intended to include what was dealt with in the report on maternal morbidity under the heading of prenatal treatment Therefore the whole weight of the endeavours of the central Department and the local authorities would be bent upon dealing with what, according to the reports that they had to guide them, was probably the most crucial period in the cure of maternal morbidity and the reduction of maternal mortality

The Bill was read a second time, and the financial resolution in connexion with it was afterwards agreed to in Committee

In the House of Lords on Feb 2nd the Ministry of Health Provisional Order (Evesham and Pershore Joint Hospital District) Bill was read a first time.

QUESTION TIME

WEDNESDAY, JAN 27TH

Experiments on Animals

Mr **Sandys** asked the Home Secretary whether he could give figures to show the average annual number of surgical experiments performed upon animals by vivisectors without the use of an anæsthetic, and what steps were taken by his department to ensure that the potential gain to scientific knowledge was commensurate with the suffering caused —Mr **Geoffrey Lloyd**, Under Secretary, Home Office, replied I presume my hon friend refers to severe surgical experiments which usually involve cutting operations The Cruelty to Animals Act, 1876, provides that experiments may be performed without anæsthetics on a certificate, called Certificate A, being given that insensibility cannot be produced without necessarily frustrating the object of such experiments Before my right hon friend allows any such certificate to come into operation he always attaches to the Licence a condition whereby no operative procedure more severe than simple inoculation or superficial venesection may be adopted in any of the experiments enumerated in the certificate The kind of experiments to which I presume my hon. friend refers are therefore never allowed without anæsthetics and consequently the second part of the question does not arise

Death-rate among Pensioners

Mr **Rhys Davies** asked the Minister of Pensions if he would state the death rate among adult male pensioners for each of the groups, 30 to 40 years of age, 40 to 45, and 45 to 50 —Mr **Ramsbotham** replied The death rates per thousand of adult male disability pensioners (Other Ranks) calculated for each of the age groups specified for the year ended 31st March, 1936, were as follows For comparative purposes the death rates for the corresponding groups of the civil (male) population have been added

Age-group	Death rate	Civilian.
35–39 years	7 1	4 8
40–44 ,	8 7	6 4
45–49	14 4	9 3

As there are only 250 pensioners under 35 years of age the age group 35–39 has been adopted

THURSDAY JAN 28TH

State Management of the Drink Traffic

Mr LOVAT FRASER asked the Home Secretary if in view of the statement by the Select Committee on Estimates that the cost of the London office for the State management of the drink traffic in Carlisle Gretna and Cromarty appeared to be excessive he had taken or proposes to take any action and if in view of the recommendation of the Select Committee on Estimates that the *whole organisation of the scheme for the State management* of the drink traffic in Carlisle Gretna, and Cromarty should be reconsidered he proposed to take any action.—Sir JOHN SIMON replied: The recommendations of the Select Committee have been considered by my right hon friend the Secretary of State for Scotland and myself. Making allowance for the fact that the cost of the London Office referred to by the committee includes the cost of the architect and his staff the room for any saving in this item appears to be small, but I am considering whether any reduction will be practicable. After reviewing the general organisation of the undertakings in England and Scotland my right hon friend and I do not propose to alter the existing system. This does not of course preclude consideration from time to time of possible improvements in the organisation.

Health Insurance Ophthalmic Regulations

Mr EDWARD WILLIAMS asked the Minister of Health whether he had considered the representations from the Institute of Chemist Opticians and other pharmacists as regards national health insurance ophthalmic and optical benefits in draft Statutory Rules and Orders, 1936 *No 434* and *what action he proposed to take in view* of these representations.—Sir KINGSLEY WOOD replied: The representations which have been made on behalf of the Institute of Chemist-Opticians will be brought to the notice of the Approved Committee to be set up under the new regulations. This committee is to include representatives of approved societies and organisations of opticians amongst which I understand that the Institute of Chemist-Opticians is to be included and it will be the duty of the committee to determine the qualifications which will entitle opticians to inclusion in a list of those to be recognised for the purposes of ophthalmic benefit.

British Pharmacists and Anti-Gas Work

Mr MITCHELL asked the Home Secretary what precise arrangements were to be made for training British pharmacists in anti gas work and whether any retaining fees would be paid to pharmacists for their assistance in the anti-gas scheme.—Mr GEOFFREY LLOYD replied: The Pharmaceutical Society generously offered the coöperation of its members in connexion with air raid precautions, and this offer was gratefully accepted. After discussion it was agreed that in the event of an emergency pharmacists could probably give the greatest service by carrying on with their *ordinary work. Arrangements* will be made as soon as possible for a number of places at the Civilian Anti-Gas School to be reserved for members of the society who will be trained as instructors with a view to their training other members of the Society in anti gas precautions. The answer to the second part of the question is in the negative.

Scarlet Fever in Doncaster

Mr SHORT asked the Minister of Health the additional cost to the ratepayers of Doncaster and the rural area, respectively due to the recent scarlet fever epidemic.—Sir KINGSLEY WOOD *replied: I am informed* that the additional cost to the rates due to the recent outbreak of scarlet fever caused by infected milk, is at present estimated at £305 in the borough of Doncaster and £70 in the rural district.

Hollywood Mental Hospital Medical Staff

Sir ARNOLD WILSON asked the Minister of Health whether any inquiry had been or would be held by his department as to the circumstances in which a medical practitioner at Hollywood Mental Hospital was retained on the staff although to the knowledge of the chief resident medical officer as stated at the inquest on the body of the man in question, he had been drinking heavily for the past eight years, and whether he was satisfied that the charge of mentally afflicted persons could safely be entrusted to men so affected.—Sir KINGSLEY WOOD replied: I am aware of the press report of statements made at the inquest referred to and I am in communication with the committee of the hospital. I should like to say however that the hospital in question has maintained a high standard in the care and treatment of the patients.

Deaths at Papworth Sanatorium

Mr ROWSON asked the Minister of Health the total number of deaths from tuberculosis and other causes which had occurred at Papworth Sanatorium, Cambridgeshire and also in Papworth Village Settlement during the past seven years.—Sir KINGSLEY WOOD replied: I am informed by the authorities of the Cambridgeshire Tuberculosis Colony Papworth that the total number of deaths which have occurred in the colony's hospital during the last seven years is 339 of which 28 were deaths of persons transferred from the Village Settlement and that the number of deaths actually occurring in the Village Settlement during the same period was 13. I cannot at present state the precise proportion of these deaths which were due to tuberculosis but I am making inquiries and will inform the hon Member of the result. I should add that the colony receives patients in all stages of tuberculosis including advanced cases.

Captain HEILGERS: Is it not a pity that anything should be said which might damage the reputation of an institution which has done most effective work for sufferers from tuberculosis?

Sir KINGSLEY WOOD: I did not understand that that was the case. This is however a fine example of the excellent work which is being done in the matter.

Papworth Sanatorium Employment of Patients

Mr ROWSON asked the Minister of Health if he was aware that persons suffering seriously from tuberculosis were employed in factories at Papworth and in some cases so employed until a few days before death; and if he would have an inquiry made into this situation.—*Sir KINGSLEY WOOD replied: I am making inquiries into* this matter and will inform the hon. Member of the result.

The Budget and Family Allowances

Mr RANKIN asked the Chancellor of the Exchequer whether his attention had been called to the rapid decline in population which was expected to take place in this country during the next 25 years; and whether in view of the difficulties which such a reduction would cause from the point of view of revenue he would give special consideration in connexion with his forthcoming budget to a further increase in family allowances.—Mr CHAMBERLAIN *replied:* My hon friend may rest assured that all relevant factors will be taken into consideration in framing the budget.

Maternal Mortality in Edinburgh and Glasgow

Mr GUY asked the Secretary of State for Scotland the figures for maternal mortality per thousand births in Edinburgh and Glasgow respectively for the last three years.—Mr ELLIOT replied: The rates of maternal mortality per 1000 births for 1934 1935 and 1936 were in the case of Edinburgh 5·3 6·3 and 5·[illegible] and in the case of Glasgow 6·0 7·0 and 5·0. The 1936 rates are provisional.

Alcohol and Road Accidents

Mr HARDIE asked the Minister of Transport if he was aware that a motorist convicted at the Old Bailey on Jan 10th for dangerous driving was charged by the judge as one of those who killed people on the road because they drink more than they ought; and whether as this and similar cases were not entered in the annual statistics as accidents due to drink, he would have the method of collection revised so that the statistics might be a fairer reflection of the facts concerning alcohol and road accidents —Mr HORE BELISHA replied Road accidents attributable to drink or drugs are already so classified In the case in question a sentence of six months in the Second Division accompanied by a suspension of licence for seven years was recorded on a conviction for dangerous driving The judge observed that the person convicted was "in a sort of twilight of sobriety" but there is no special subhead for this condition

Basement Dwellings in London

Mr LYONS asked the Minister of Health if any recent investigations had been made into the number and nature of basement dwellings in various parts of London and with what results —Sir KINGSLEY WOOD replied The most recent investigation was made in 1934 According to the returns then obtained by the London County Council from the metropolitan borough councils, 20 108 underground rooms in use for sleeping purposes were deemed to be unfit for human habitation within the meaning of section 18 of the Housing Act, 1925

MONDAY, FEB 1ST

Government Employees in Basement Offices

Lieut Commander FLETCHER asked the Parliamentary Secretary to the Ministry of Health, as representing the First Commissioner of Works, if he had received any representations concerning Government employees compelled to work in basement offices, and, if so, what departments were concerned and what action was proposed —Mr R S HUDSON replied Representations have been received by my noble friend from the Staff Sides of the Departmental Whitley Councils for the Board of Education, Ministry of Health, Board of Trade and Office of Works concerning the continued use by clerical staffs of the basement courts of the Government Offices, Westminster, Southern Block. Pending the vacation of the basement courts, in accordance with the arrangements as originally planned, consideration is being given to the points raised by the staffs as to the detailed working of the ventilation arrangements and the improvement of the access to the basement

Physical Training in Schools

Mr SHORT asked the President of the Board of Education how many local educational authorities had appointed special organisers for physical training, and whether Doncaster was among the number —Mr G SHAKESPEARE, Parliamentary Secretary to the Board of Education, replied 170 local education authorities have appointed one or more whole time or part time organisers of physical training and a number of other authorities are considering the question of making such appointments The number of organisers now employed by local education authorities is 236 A proposal for the appointment of organisers has not yet been received from the Doncaster authority, but it is understood that the authority are considering the matter, and the Board wrote to them on Dec 1st last calling their attention to its importance

Children's Branch of Home Office

Mr LOVAT FRASER asked the Home Secretary why his office had ceased to issue reports of the children's branch —Mr GEOFFREY LLOYD Under Secretary, Home Office, replied There are a number of reasons—in particular the additional labour involved in the preparation and bringing into force of the Children and Young Persons Act, 1933—which have prevented the issue of a report in recent years My right hon friend is fully aware of the value of these reports and a further report will be issued as soon as circumstances permit

Experiments among Recruits Below Standard

Mr BELLENGER asked the Secretary of State for War whether he could make a statement on the experiment of special training and nourishment for certain selected recruits under standard, and whether he proposed to extend the experiment to include large numbers of recruits now rejected as unfit —Mr DUFF COOPER replied At the end of the initial three months' training, 31 of the 33 recruits who had been selected for experiment were adjudged to be fit to start the normal recruits' course and were passed to their regimental depôts for this purpose Twenty four have since been passed as up to standard, while 7, who have not yet reached normal standard, but have made such progress as to justify their retention, are under special observation at their depots The experiment is regarded as successful, and its practical application on a larger scale is under consideration

Government's Physical Training Scheme

Mr SANDYS asked the President of the Board of Education whether he could announce the Government's plans for improving the national standard of physical fitness —Mr OLIVER STANLEY replied I hope that a White Paper explaining the Government's proposals will be issued on Thursday next

B.M.A and Medicine Advertisements in Stamp Books

Sir NICHOLAS GRATTAN DOYLE asked the Postmaster General whether he had received representations from the British Medical Association respecting certain classes of advertisements appearing in the books of stamps issued by the Post Office, and whether he proposed to take action in the matter —Sir W J WOMERSLEY, Assistant Postmaster General, replied Representations on this subject were received from the British Medical Association a few years ago My right hon friend recently reviewed the matter in connexion with a question asked on Dec 7th last, and found no reason for altering the present policy, which is to exclude advertisements of medicines purporting to cure certain diseases specified in Paragraph 58 of the Report of the Select Committee on Patent Medicines, 1914, but to accept other advertisements whose wording is not objectionable and whose bona fides is not suspect

A CLEARING-HOUSE FOR HOSPITAL EMERGENCIES IN LONDON

THE Voluntary Hospitals Committee for the county of London, which since its constitution in July, 1935, has done so much to make the voluntary principle effective, has now embarked on a new and ambitious scheme It is nothing less than the provision of a central office to facilitate the admission to voluntary hospitals of emergency and acute cases There are already arrangements for the transference of accident cases from voluntary to municipal hospitals, and these are now being extended by arrangement with county councils outside London, but apart from accidents it still happens that a doctor who is in urgent need of a bed for an acutely ill patient has to ring up a number of hospitals before he can find one A central office would be able to tell him forthwith where to send his patient, and would warn the hospital of the patient's impending arrival It is difficult to see whether doctor, hospital, or patient would gain the more by such a clearing house All the hospitals have been consulted and nearly 100 have replied, 61 of them have expressed willingness to coöperate in the proposal, and only 3 stand out This unusual degree of unanimity should ensure the success of the scheme if it is in the hands of promoters who admit no discouragement The working out of the proposal has been remitted to a committee consisting of Dr A M H Gray, Dr Geoffrey Evans, with the chairman and hon sec (Prof L S Dudgeon) of the committee, and Mr A J Gardham, F R C S, and Mr C M Power as coöpted members

PUBLIC HEALTH

Accredited Milk

ON Jan. 28th a conference was held at the Central Hall Westminster under the auspices of the Royal Sanitary Institute and attended by delegates from all over the country to consider the administration of the Milk (Special Designations) Order 1936 with respect to accredited milk. Mr THOMAS BAXTER, chairman of the Milk Marketing Board presided and explained the aims of the Board in establishing a roll of accredited producers

The discussion was opened by Dr W G SAVAGE medical officer of health for Somerset, who pointed out that while on paper there was reasonable uniformity in practical working there were material divergencies Three requirements he regarded as essential (1) compliance with the Milk and Dairies Order 1926 (2) provision and utilisation of efficient means of steam sterilisation (3) provision of certain minor equipment essential for clean milk production The main divergence arose over the first requirement owing to the vagueness in the wording of the order and the different interpretations placed on its enforcement. Uniformity of administration suffered from the varied types of officer employed to carry out the inspections but this did not matter much for the only basis on which uniformity of practice could be attained was uniformity of knowledge The inspecting officer should be one who had acquired special experience in clean milk production Clean milk production could not be controlled by printed requirements suitable premises were necessary but they were not so important as trustworthy methods

Mr F W MEDLOCK chief veterinary officer to the Essex C C dealt with the veterinary aspects of the problem and discussed the difficulties of laboratory sampling.

Mr F H LONG chief sanitary inspector to the Hereford R D C insisted that the local sanitary authorities and their inspectors were responsible for the operation of most of the order and that their coöperation was essential. He admitted the wide differences of administrative practice

Mr W T PRICE agricultural organiser to the Wilts C C dwelt on the agricultural side and the need to associate the organisers with the work

VETERINARY CONTROL

When the meeting was thrown open to discussion many persons prominent in milk control took part each speaker emphasising the importance of the particular office or section which he represented There was however a general feeling that it should be possible for the various interests to get together and evolve a scheme for more uniform administration

Several veterinary officers present regarded Dr Savage's remark on the value to the accredited milk scheme of veterinary inspection as a criticism of the value of veterinary work generally Dr Savage replied that he was strongly in favour of enlisting veterinary surgeons in any scheme for improving the milk supply—he was in fact himself largely responsible for whole-time veterinary surgeons having been appointed in his own county—but he felt they were misapplied in routine veterinary inspection and should be utilised mainly to build up herds free from tuberculosis. The words to which exception were taken were Personally I do not regard the veterinary control required as materially influencing its safety —and this was Dr Savage suggested a scientific matter capable of being judged by the application of scientific facts. He agreed that the quarterly veterinary inspection required under the Accredited Scheme was of service to the milk producer but it did not materially influence the safety of the milk. Most of the conditions detected, of which mastitis was the commonest were of importance in relation to the health of the herd but of no moment as regards human safety for they were not transmissible to man The veterinary control did not concern itself with undulant fever and practically the only disease which came into question was tuberculosis But this control had no effect on the incidence of bovine tuberculosis and indeed no such effect was to be anticipated Some slight reduction might be expected in the incidence of tubercle bacilli in the milk but examinations of Grade A or accredited milk all over the country showed still a high proportion of samples containing tubercle bacilli. For 1936 in Somerset of all the 442 samples collected at farms 3 3 per cent were positive in the samples from accredited farms taken separately the percentage was not smaller Veterinary control did not alas! materially influence the safety of accredited milk.

Ophthalmia Neonatorum

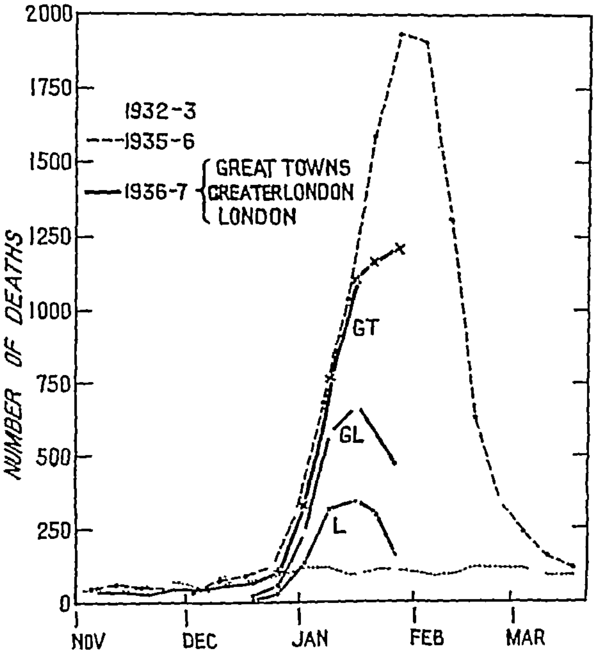
It is the statutory duty of the maternity and child welfare authority to give assistance in cases of ophthalmia neonatorum by providing nursing in the home and if deemed advisable hospital treatment outside it The time element is important as the value of treatment depends chiefly on the speed with which it is given But this authority does not now receive as by right the information it needs to do this; it comes only indirectly through the county authority The Ministry of Health has been urged to arrange that ophthalmia should be notified directly to the M.O H of the M and C W authority and this will be ensured as from April 1st next by new regulations (1937 No 35) The M O H of a district council which is not a M. and C W authority will now receive from the county M O H prompt information of any cases occurring in his district and contrariwise the county M.O H will learn of all cases which occur in the administrative county The new arrangement although it sounds complicated will simplify procedure and will ensure that the baby whose eyes are in danger gets the right kind of attention in the shortest time

The Welsh Tuberculosis Scheme

A frank discussion took place last week between the King Edward VII Welsh Memorial Association and the contributing authorities Lord Davies who presided, admitted that the hopes of rapid progress with which the Association started twenty years ago had not been realised. The mortality rate of tuberculosis per 100 000 of the Welsh population had only dropped in the period from 110 to 92 compared with a drop in England from 103 to 70 and in Scotland from 111 to 74 The Association is proposing to build a new tuberculosis hospital of 250 beds at Swansea and to form a nucleus of two village settlements the total expenditure for the five year period being estimated at nearly £[illegible]00 000 The contributing authorities complained that the halfpenny rate of 1912 had increased to a fivepenny rate in counties like Flint and they were spending on tuber culosis more than half the whole outlay on public *health services* The scheme is to be further considered by financial experts

Influenza

Last week influenza accounted for 1155 deaths in England and Wales, and for 154 deaths in London Reference to the graph will show better than words the trend of the epidemic up to Saturday last In the previous week although London had passed the peak the midland and northern areas were still showing higher returns—e g, Birmingham 51, Nottingham 26, Sheffield 49, and Manchester 41 deaths While in London we are breathing freely—the notifications of pneumonia last week dropped from 326 to 211—the situation in the north is less satisfactory In Liverpool for example many cases are being admitted to hospital with capillary bronchitis, and extreme prostration is a feature even of uncomplicated cases In Sheffield there were 65 deaths last week Throughout Scotland the epidemic is still causing inconvenience Practitioners on the whole, however, are less busy than they were two weeks ago, and in Edinburgh there is an impression that the worst is over Although last week's death roll was the highest since the 1929 epidemic, 78 per cent of those who died were over the age of 45 In Dublin influenza has become more widespread and many business establishments are suffering from depletion of staffs In several hospitals inconvenience has arisen from the large number of nurses ill, and some visiting staffs are suffering heavily The type of disease has not generally been grave



Graph showing total deaths from influenza in the Great Towns on the last day of each week in three different years

Small-pox in Failsworth

The two cases of small pox notified in a recent return from Failsworth illustrate the difficulties of dealing with the disease when it occurs in so mild a form On Jan 11th Mrs A, aged 62, was removed to Hartshead small pox hospital She had taken ill on Jan 3rd with headache and pains in the back, and the rash appeared on Jan 6th. She had been vaccinated in infancy but not since. Her illness ran a mild course, and she was discharged on Jan 29th. The urban district of Failsworth is contiguous to Oldham where a small outbreak occurred in December, but it was only after intensive oblique inquiry that it was discovered that Mrs A's sister, Miss B, aged 72, living in the same house, had been indisposed from Dec 21st to 23rd, and when examined on Jan 12th was found to have a fading rash on face and forearms The diagnosis was confirmed the following day, and Miss B was removed to the small pox hospital from which she was discharged well on Jan 22nd. She had been vaccinated in infancy and again on Jan 11th after removal of her sister On further inquiry it turned out that Miss B had visited at the two houses in Oldham where the four previous cases had occurred The patients were in fact her near relations, and the Failsworth cases were thus brought into their natural relation with the Oldham outbreak All the contacts in the Failsworth house have been revaccinated, as well as the staff of the public health department and the doctors in attendance

---

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 23RD, 1937

Notifications—The following cases of infectious disease were notified during the week Small pox, 0, scarlet fever, 1671, diphtheria, 1294, enteric fever, 61, pneumonia (primary or influenzal), 3135, puerperal fever, 42, puerperal pyrexia, 147, cerebro spinal fever 34, acute poliomyelitis, 3, encephalitis lethargica, 10, dysentery, 21, ophthalmia neonatorum, 72 No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan 29th was 3701, which included Scarlet fever, 833 diphtheria, 1014 measles 17 whooping cough 582 puerperal fever 19 mothers (plus 8 babies), encephalitis lethargica 286 poliomyelitis 2 At St. Margaret's Hospital there were 20 babies (plus 8 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns, including London, there was no death from small-pox, 4 (0) from enteric fever, 6 (0) from measles, 5 (1) from scarlet fever, 28 (7) from whooping-cough, 34 (7) from diphtheria, 33 (10) from diarrhœa and enteritis under two years, and 1137 (273) from influenza The figures in parentheses are those for London itself

Liverpool reported all the 4 deaths from enteric fever Middlesbrough had 3 deaths from whooping-cough, Stockton on Tees and Grimsby each 2 Fatal cases of diphtheria were reported from 17 great towns Hull and Liverpool each 4 Manchester and Sheffield each 3

The number of stillbirths notified during the week was 308 (corresponding to a rate of 48 per 1000 total births), including 37 in London

---

Leicester City Hospital—Leicester health committee on Jan 22nd passed plans for extensions at this hospital which will include accommodation for the aged, and chronic sick, and a new nurses' home The estimated cost of the scheme is given as £300,000

Westminster Hospital—As a result of the festival dinner held at the Mansion House in aid of this hospital £12,900 has been collected towards the Coronation wing of the new building and £1000 as an endowment of which the income is to be used to provide additional comforts for nurses and extra holidays for convalescent nurses

MEDICAL NEWS

University of Oxford

Mr Hugh Cairns has been appointed to the Nuffield chair of surgery and Dr R R Macintosh to the Nuffield chair of anæsthetics

Mr Cairns, who is 40 years of age was educated at the Adelaide High School and is a medical graduate of Adelaide University where he was exhibitioner Davies-Thomas scholar and Everard scholar After serving with the Australian Army Medical Corps he entered Balliol College as a Rhodes scholar in 1919 He worked in the department of physiology and rowed in the Oxford boat in 1920 He was house surgeon at the Radcliffe Infirmary in 1921 and in the same year went to the London Hospital serving successively as house surgeon, house physician pathological assistant and first assistant in the surgical unit He took the fellowship of the Royal College of Surgeons of England in 1921 In 1926 he was elected to the staff of the London Hospital and was then given leave of absence to go with a Rockefeller fellowship to the United States where he became for a year assistant resident surgeon in Dr Harvey Cushing's clinic in Boston On his return he wrote a "Study of Intracranial Surgery" which the Medical Research Council published in its special report series (No 125) Since then after some years on the general surgical staff he has established at the London Hospital a department of neurosurgery largely inspired by Cushing's ideals A recent paper which illustrated his continued association with the Boston clinic and the methods employed both there and in London is his account of the fate of patients operated on for intracranial tumour during his visit to the United States in 1926 (THE LANCET 1936 i, 1223, 1291) Mr Cairns has also written much on brain abscess and head injuries and their treatment and in 1926 before devoting himself to intracranial surgery he gave a Hunterian lecture to the Royal College of Surgeons of England on neoplasms of the testicle In 1935 he was awarded the triennial gold medal of the West London Medico-Chirurgical Society He is also honorary surgeon to the National Hospital, Queen-square

Dr Macintosh who is 39 is a former student of Guy's Hospital. He qualified in 1924 and two years later obtained the fellowship of the Royal College of Surgeons of Edinburgh His post-graduate experience included appointments in the venereal diseases department of Guy's at Lambeth Hospital and at the British Hospital at Montevideo (Uruguay), where he was resident surgical officer On returning to England he began to practise as an anæsthetist with an honorary appointment in the dental school at Guy's He is now anæsthetist to the Throat Hospital, Golden-square and anæsthetist and lecturer in anæsthetics in the dental department of University College Hospital He has written on blood transfusion and on anæsthetics in dental surgery and a few years ago contributed to the Battle of the Barbiturates in our correspondence columns where he wrote of the importance of developing methods of pre-anæsthetic medication

Prof Cairns's appointment dates from Jan 27th and Prof Macintosh's from Feb 17th It is understood however that their duties will at present allow them to go on with their work in London.

Royal College of Physicians of London

A comitia of the College was held on Jan 28th with Viscount Dawson of Penn the president in the chair The election of the president as a vice-president of the Imperial Cancer Research Fund was approved and Dr E Mapother was elected a councillor The following were appointed delegates of the College: Lord Dawson of Penn to the centenary celebrations of the University of Durham July 1st to 3rd; Dr H P Newsholme to the health congress of the Royal Sanitary Institute at Birmingham July 12th to 17th; Lord Horder to the annual congress of the Royal Institute of Public Health at Margate May 25th to 29th and Dr H C Cameron to the seventh English-Speaking Conference on Maternity and Child Welfare to be held in London June 1st to 3rd

Dr D'Arcy Hart will deliver the Milroy lectures on measures for the prevention of pulmonary tuberculosis among adults in England—in the past and in the future on Feb 18th and 23rd; Dr D L Denny Brown the Goulstonian lectures on the nervous control of micturition and its disorders on Feb 25th March 2nd and 4th Dr Crighton Bramwell the Lumleian lectures on the arterial pulse in health and disease on March 9th and 11th; and Dr H Gardiner Hill the Oliver Sharpey lectures on growth and development their pathological aspects on March 16th and 18th. All the lectures will be given at the College at 5 P.M The following candidates having satisfied the censors board were admitted members of the College:—

Frank Longstaff Apperly, M D Oxon M D M B Bidya Pati Bhattacharjya M B Patna Bernard Roy Bramwell, M B Toronto John M D Manch Francis Staples Brien Alfred Brocklebank M B Lond George Horace Brookman, L.R.C.P Lond James William Douglas Bull, M B Camb Renfrey Gershon Burnard, M B Adelaide Archibald Malcolm Gordon Campbell, M B Oxon Winston Stephen Charters M B N.Z. Stephen Thomas Falla, M.D Lond, John Ronald Forbes M.B Lond, Graham William Hayward M.B Lond. Diplomas were granted, jointly with the Royal College of Surgeons, to the following candidates —

Tropical Medicine and Hygiene.—R M Abraham E E Barnett H B F Dixon I K El Lamii W J Pinto, G B Smart and P W Vilain

Diplomas in anæsthetics were also granted to those candidates mentioned in The Lancet of Dec 19th, p 1497, and diplomas in public health, psychological medicine and laryngology and otology to those mentioned in The Lancet of Jan 23rd, p 242

University of Edinburgh

At a recent meeting of the university court it was announced that the University Grants Committee had offered a non recurrent capital grant, up to a maximum of £15,000, towards the cost of building a students' union for men and women on the King's Buildings site at Westmains road The building will include a refectory and gymnasium The total cost is estimated at £20,000 and the committee offered a grant on condition that the balance is obtained from other sources and that the scheme is proceeded with as soon as possible—in any case, within two years The present students' unions are too far from the New University at King's Buildings for them to be of much value to the increasing number of students who spend a large part of their day in the new buildings

Scottish Conjoint Board

At recent examinations by the board of the Royal Colleges of Physicians and of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates were successful —

Empire Tuberculosis Conference

A conference on the care and after-care of the tuberculous is to be held at Overseas House, St James's, from May 3rd to 8th, under the auspices of the Overseas League and Papworth Village Settlement The subject for the first day is the Fight against Tuberculosis throughout the Empire to be introduced by Sir Kingsley Wood and Prof S Lyle Cummins, for the second day, the After care of the Tuberculous throughout the Empire, to be introduced by Sir Pendrill Varrier-Jones and Dr B A Dormer, on the third day Lieut Colonel G G Jolly, I M S, and Dr P V G Benjamin will introduce the subject of the Native Races and Tuberculosis throughout the Empire At a recent informal meeting Lord Willingdon, who will preside at the conference explained what an unrivalled opportunity the Coronation offered of getting together interested people from all parts of the Empire Sir Pendrill said that, as tuberculosis had been introduced by the white man to races which had hitherto been free from it it was part of our Imperial responsibility to combat the disease on every front, social and economic as well as medical Little progress would be made, he felt, unless the victims of tuberculosis were given an opportunity of working and earning in a suitable environment Prof Cummins spoke of the conference as an essential step to the better comprehension of the problem of preventing and curing tuberculosis in the native populations which had shown themselves intensely susceptible to tuberculosis when brought under industrial conditions A preliminary programme of the conference may be had from the hon secretary, Empire Conference (Tuberculosis), Overseas House, St James's, London, S W 1

University of Liverpool

On Thursday Feb 11th, Mr Walter Mercer, lecturer in clinical surgery in the University of Edinburgh will deliver the Lady Jones lecture in orthopædic surgery to the University He will speak at 4 P M in the medical school, and his subject will be anomalies of the fifth lumbar vertebræ The lecture is open to members of the medical profession

Royal Society of Medicine

At 8 30 P M on Thursday, Feb 11th Sir John Parsons, F R S, the president, will receive fellows of the Royal Society of Medicine and their friends at the society's house, 1, Wimpole street, W At 9 15 P M Dr T Graham Brown, F R S, professor of physiology in the University of Wales, will give an illustrated address on mountain climbing in three continents

Improvement of Eyesight

Opening the Exhibition of Ophthalmic Goods and Equipment at the Royal Horticultural Hall last Tuesday, Sir Kingsley Wood, Minister of Health, said that though the total amount of eye deficiency showed little sign of abating the incidence had to some extent been shifted to the later years of life, and much was being done in the prevention of blindness He mentioned that whereas before the late war some 90 per cent of the spectacle lenses used in this country were of foreign manufacture, the proportion had now fallen to about 25 per cent

Association of Industrial Medical Officers

The sixth meeting of this association was held at the London School of Hygiene on Jan 22nd, Dr N Howard Mummery being in the chair —Prof Millais Culpin discussed the recent development of medical psychology, showing how it represented in some ways a return to earlier conceptions, with a swing of the pendulum towards the recognition of psychological factors Sickness incidence varied in its diagnostic distribution in accordance with fashion, neuritis and traumatic neurasthenia for example tending to disappear He remarked on the curious inability to diagnose common psychoneurotic conditions There were medical men who repudiated the psychological point of view and were therefore prone to miss such cases and to live in a happy state of unjustified certainty —Miss May Smith, D Sc, described the historical evolution of modern industrial psychology, and put forward a plea for a more intelligent understanding of the human factor in industrial medical practice The industrial medical officer, she maintained, should be the main link between industry and the work of the Industrial Health Research Board

At the quarterly dinner held the same evening in the School of Hygiene Dr Mummery was presented with an inscribed silver tray on his retirement from the chairmanship In making the presentation Prof W W Jameson paid tribute to his pioneer work after the War in the establishment of the modern industrial clinic Dr Leonard P Lockhart succeeds Dr Mummery in the chair

The People's League of Health

At a luncheon on Jan 19th in the Savoy Hotel, London, Lord Leverhulme asked for the coöperation of the press and of the officers of the People's League of Health in its first national appeal The League, he said, was founded in 1917 by Miss Olga Nethersole, and its objects were expressed by the adage "prevention is better than cure" It was trying to remove the disease, wastage and suffering that were due to ignorance and to bad environment and nutrition To this end the League published a great variety of authoritative pamphlets disseminated leaflets, and posters, promoted health weeks and exhibitions, instituted courses of lectures at various centres, and had awarded eleven travelling scholarships Through its inquiry bureau it was helping individuals and institutions seeking advice on matters of health and the prevention of disease Special committees had investigated specific problems and when the League's findings were conclusive they had been impressed upon the Government by various deputations such as those on the effects of unemployment on juvenile delinquency, and on noise Other important inquiries included those into tuberculosis and milk, leading to the safe milk campaign, and

NOTES, COMMENTS, AND ABSTRACTS

THE FUTURE STATUS OF THE CLINICAL PATHOLOGIST *

BY S C DYKE D M. F R C.P

PATHOLOGIST TO THE ROYAL HOSPITAL, WOLVERHAMPTON
CLINICAL PATHOLOGIST TO THE GENERAL HOSPITAL, WALSALL

THE declared and avowed clinical pathologist is a comparatively recent entrant into the field of medicine in this country I suppose that in the whole of Great Britain and Ireland there are not more than 250 medical men and women who would regard themselves as falling within the category The number is growing and seems likely to continue to do so the time is ripe for a consideration of the sphere of the clinical pathologist, of the sort of training required to fit him for his work, and of his status in relation to his fellow medical practitioners

Clinical pathology may be defined as the application of pathology and of the methods of pathology to clinical medicine Time was when all pathology was more or less clinical and many of the founders of British medicine might be described as clinical pathologists Bright Addison Hunter Gull and Sutton and many others fall within the terms of the definition. But since the days of the giants of old a gulf has opened between clinical medicine and pathology Some pathologists have tended to pursue the study of their subject for its own sake and without reference to clinical medicine and some clinicians have shown a reluctance—often amounting to a positive aversion—to admit the application of the methods of pathology to clinical medicine

As an example, incredible though it may sound I lately heard an eminent physician address an audience of medical men and women for a full hour and a half on the subject of obscure pyrexia without once making mention of any laboratory method. Even in the diagnosis of coliform infection of the urinary tract his recommended methods of investigation did not pass beyond the observation of smell and naked-eye appearance of the urine

THE CLINICAL PATHOLOGIST AS SPECIALIST

It is the aim of clinical pathology to enlarge and extend the boundaries of clinical observation beyond those attainable by the unaided senses In its own sphere it endeavours to introduce scientific precision into medicine The question whether or not medicine is a science has on occasion served as a subject of rather futile debate In so far as it is founded upon a body of reasoned knowledge and systematised experience it is a science The reasoning upon which some of of our present day medical practice is based will probably not for ever appear sound and its supposed fundamentals will require alteration and amendment but this is a state of affairs common to all sciences even the mathematical the principles of which not so long ago appeared to be immutably fixed for all time to come.

So far as medicine is a science it is founded upon physiology and upon pathology which is morbid physiology The sphere of clinical pathology is the practice and pursuit of pathology and therefore of physiology in so far as they come into contact with clinical medicine. The extent to which they will so come into contact must increase with the progressive establishment of medicine upon the basis of science

But pathology and physiology form a large part of the medical curriculum and are common ground to all those who endeavour to practise medicine in a spirit of other than pure empiricism. Something more than a knowledge and appreciation of the relation of these subjects to clinical medicine is necessary for the clinical pathologist. Not only must he know the theory but he must in addition have full mastery of the technique of his subject that technique is largely that of the laboratory

It is the existence of this technique which makes it necessary to regard clinical pathology as a special branch of medicine. Whether its practitioners should rightly be regarded as specialists is a matter of no great moment. The best definition of this much abused term with which I am acquainted I heard from Sir Cuthbert Wallace it was if I remember rightly to the effect that only those should be regarded as specialists who have the mastery of some special technique. In the case of the clinical pathologist the technique is that of the laboratory and he falls within the terms of the definition

A mastery of laboratory technique is neither easily nor quickly acquired. In certain teaching schools the belief appears to prevail that by virtue of a short course of tuition in laboratory methods the student will after qualification be in a position to apply for himself and upon his own patients the methods of laboratory diagnosis Personally I believe this to be a fallacy and the time spent in instructing the medical student in the technique of laboratory methods to be largely wasted. It is essential that the medical man have a general idea of the nature and scope of these methods in the study of disease that he should understand their practical applications in diagnosis and in particular that he should harbour a lively sense of their limitations in that field. The most assiduous application over a few months to a course of instruction practical and otherwise cannot however make a medical student into a skilled laboratory worker—much less endow him with a full knowledge of the application and interpretation of the results of diagnostic laboratory work Furthermore few medical men engaged in clinical practice have the time to devote themselves personally to the application of any but the simplest laboratory methods to their own cases. That this is so is probably not all to the bad. Could and would every medical man study his own cases in his own laboratory it would undoubtedly add interest to practice just as interest is added to that practice in which the practitioner is his own surgeon But by common consent such an arrangement is not always in the best interests of the patient The same I believe to apply to clinical pathology

The technique of the diagnostic laboratory is the special field of the clinical pathologist and the laboratory must play a large part in his training The medical student who is drawn to the practice of this specialty will almost certainly have paid particular attention to physiology and will have more than a speaking acquaintance with the technique of that science A thorough grounding in the technique of physiology will carry him far in the clinical pathological laboratory The technique of biochemistry and histology will present little unfamiliar that of bacteriology and serology will not be entirely strange

---

* Presidential address to the Association of Clinical Pathologists on Jan 29th

I think that the ideal department for the training of the clinical pathologist is that in which all the laboratory diagnostic work and the post mortem service of a general hospital is conducted under one head, in such a department the danger of undue specialisation on any one branch is easily avoided, this is not so easy in larger institutions in which specialisation has led to the formation of separate and distinct departments, but even in the face of such departmentalisation coördination can be and often is maintained.

THE CLINICAL PATHOLOGIST AS CLINICIAN

It is his mastery of his special technique that is the excuse for the existence of the clinical pathologist Also it is essential that he be more than a mere specialist The dangers of "narrow specialisation" in all branches of medicine are now so widely apparent that it is not necessary to dilate upon them If he is to fill his proper sphere the clinical pathologist must by all means avoid these dangers A thorough acquaintance with clinical medicine is as necessary to him as it is to the surgeon, the cardiologist, the ophthalmologist, or the practitioner in any other special branch of medicine Clinical pathology has no place for the pure laboratory bench worker He has a place and a very honoured place in other branches of pathology, but clinical pathology is only partly a matter of the laboratory bench, equally it has its place in the wards and at the bedside

Without a thorough knowledge of the problems of clinical medicine the clinical pathologist is in no position to fulfil the whole of his function and such knowledge is only to be acquired in the wards His place is not wholly in the laboratory, and routine work at the bench is not his business, he must himself have performed and be thoroughly familiar with every detail of all procedures carried out in his laboratory, unless he has done so he is in no position to supervise their performance by others Routine work can, however, equally well be done by skilled laboratory technicians and is a waste of the time of the experienced clinical pathologist His business as the head of his department is its direction and supervision And that is not the whole of his business

It is further his part to see that his department is used to the fullest and best advantage of the community which it serves, be that community a hospital, a congerie of medical men, or both The capacity to do this demands more than skill and experience in laboratory work The clinical pathologist must be able to act as a guide to the uses of his own department and to the interpretation of the results obtained in it To act as a guide he must know the geography of the avenues of approach most likely to lead to the solution of any given diagnostic problem Such knowledge comes only from acquaintance with the natural history of disease, without such knowledge the clinical pathologist will be but a blind guide That he may be able to deal with this aspect of his work it is essential that in addition to his special skill and experience in laboratory technique he possess a full knowledge of clinical medicine, the wards as well as the laboratory must constitute his training ground

My own training was acquired in the wards and the laboratories of the clinical units of St Thomas's Hospital, in my present department at The Royal Hospital, Wolverhampton, it has been my endeavour to carry on the spirit which animated the units in my time At The Royal Hospital the assistant pathologist fills also the post of resident medical officer and is charged with maintaining the closest possible liaison between the laboratory and the wards The arrangement works well so far as the laboratory is concerned, from the approval which it has gained from my colleagues on the honorary staff I believe it to be advantageous to the clinical work of the hospital and from the comments of those who have held the joint post I believe it to provide a satisfying though far from an easy life

Some such combined post is, I think, ideal for the training of the clinical pathologist By placing in the hands of the same observer the supervision both in the wards and in the laboratory of the investigation of any given case it affords the fullest opportunity for the intelligent correlation of ward and laboratory findings, in the capacity of assistant pathologist the holder of the post will perform or assist at all post mortem examinations and is thus afforded the opportunity of verifying (or otherwise) deductions from findings during life Clinical observations, laboratory data, and post mortem findings are checked against each other by the same person and all in the same department In this way an accuracy, a continuity, and a completeness of observation can be applied to the study of any given case which would I think have satisfied the ideal of my first master in medicine, the late Sir William Osler

Given a well equipped and properly staffed pathological department I believe such a post as outlined to afford the best possible training ground for the clinical pathologist Furthermore, by assuring so far as is humanly possible the full and proper use of the diagnostic facilities of the laboratory it is manifestly advantageous to the clinical work of the hospital.

The University of London some years ago, largely at the instance of the Association of Clinical Pathologists, established a diploma in clinical pathology This diploma will in future serve as the mark of the trained clinical pathologist and the time may well come when its possession will be as essential to the candidate for the post of hospital pathologist as that of the "fellowship" is for the aspirant to a place on the surgical staff As evidence, however, of his capacity to take his proper place and to fulfil his rôle in his own medical community, the complete clinical pathologist will wish also to possess some one of the higher post graduate distinctions in clinical medicine

Thus trained and equipped he will be in a position to fill his proper sphere In order that the fullest and most advantageous use be made of his special skill and knowledge it is essential that along with his fellow specialists in other branches of medicine he takes his place both in the counsels of the institution to which he is attached and in consultation at the bedside as well as in the laboratories

PATIENT OR MATERIAL FROM PATIENT?

Lord Horder recently spoke of the clinical pathologist as substituting for the study of the patient "qua patient" that of "material derived from the patient" I hope I have made it clear that this is diametrically opposed to the view of their subject held by its own practitioners The clinical pathologist does indeed study material derived from the patient and brings to that study the aid of a special technique, to him, however, his laboratory findings form only a part of the pattern of the case and he realises that unless considered in their proper relationship to the whole picture they may be of little value, sometimes worthless and not rarely actually misleading.

It is not as a rule the clinical pathologist who draws diagnostic deductions from the recovery on culture of organisms from an otherwise normal urine or who diagnoses typhoid fever from a positive Widal reaction without reference to titre or the general state of the patient it is not he who orders a vaccine made up from the normal fauna and flora of the fauces or bowel, nor is it he who will administer it But in all these things and more he may and does see his work misapplied and his name taken in vain

It used to be the fashion to speak of pathology as a science ancillary to medicine and there was at one time a tendency to treat its practitioners not so much as hand maidens as general drudges to the lords of medicine Our first president, the late Prof C Powell White throughout his working life fought both with tongue and pen against this attitude If clinical pathology is ancillary to medicine it is ancillary in the same way and to the same degree as any other special branch is ancillary to medicine as a whole. Clinical pathology has its own contribution to make towards and its own part to play in the entelechy of medicine It is the business of the members of the Association of Clinical Pathologists to see to it that its contribution is made fully and its part effectively played

A PSYCHOTHERAPIST S TRAINING

In his presidential address delivered to the British Psychological Society (Medical Section) on Jan 27th Dr H. Crichton Miller prefaced his remarks on the Frontiers of Psychotherapy by reviewing his own professional experience from which the contribution he proposed to make from the presidential chair was derived He proceeded In another place I have expressed my belief that it would be for the good of all concerned if by a Utopian scheme of medical education and practice we could have a probationary period in general practice of say five years, after qualification and before specialising in psychotherapy The ten years that I spent in general practice taught me many things that I would not have learned otherwise and taught me much that is not being taught to the aspiring psychotherapist of to-day We are all aware of the danger of narrowness in any specialised department of treatment these dangers are essentially psychological in character if we psychologists are content to live and practise in blinkers, we are *in no position* to point out to others the restriction of their field of vision.

The second element in my experience to which I owe much is that I have worked for over a quarter of a century in a nursing home which I started solely for the treatment of psychoneurotics There I have seen various psychotherapeutic techniques in operation under favourable conditions There I have seen the intangible effects of atmosphere, a therapeutic agent as elusive as vitamins and hardly less essential There I have been able to evaluate the results of thorough physical treatment on a scale that I can look back on without shame There finally I have learned how impossible it is to manufacture a psychological nurse and how deplorably low is the birth rate of this breed

The third element to which I owe much is professional work in the war And no one could go through those years without learning lessons about repression and valour, stupidity and vanity not to mention other aspects of the human psyche

The fourth element which has enriched my professional experience is the Institute of Medical Psychology which I started in 1020 as the Tavistock Clinic For 13 years I acted as director and during that time we passed through the lean years of psychotherapy—say 1925–30 when professional approval was still grudging and the Mayfair vogue had waned In those 13 years I had unusual opportunities of *observing the frontier activities* of psychotherapy with general practice with psychiatry with education and with religion Furthermore I was in a position to observe and assess the therapeutic value of a considerable number of junior colleagues In this connexion I recall certain painful conversations in which I was reluctantly obliged to point out to a zealous aspirant that he or she—as the case might be—was not sufficiently promising to begin or not sufficiently successful to continue to work with us Of the victims of what the modern undergraduate would call sadistic dictatorship some have reverted to general medicine without bearing me any malice some clearly cherish resentment to this day and one—after a lapse of ten years—has forgiven me by reason of a Group Movement conversion From this last instance I deduce and would have you deduce that the particular brand of religion referred to can achieve for some readjustments that cannot otherwise be attained. There were other victims of autocratic direction who refused to be discouraged by so undiscerning a judgment They flourish in various *other departments and schools of psycho*therapy where training is more important than a high I.Q The Clinic taught me more than I ever learned in private practice of the attitude of the general practitioner and particularly of the panel doctor towards psychotherapy On this frontier as some of you have also learned there was a strong tendency to regard psychotherapy as a form of magic This has great inconveniences—particularly for the *magician But in the last few years the practitioner's* outlook has improved immensely and it is reasonable to suppose that it will continue to improve At the Clinic as in the nursing home one saw a variety of psychotherapeutic methods in action. The only difference was that they were being applied in unfavourable conditions as opposed to the favourable conditions of the nursing home The problem of institutional versus ambulant treatment is one that *for the most part is settled by circumstances* most psychotherapists are working either in or outside an institution Therefore all their patients tend to be treated on the one basis or on the other The psycho-analyst is inevitably bound to a method of treatment from which *coöperation* with the environment is excluded But my experience has taught me that far more skilful and frequent use should be made of environment as an adjuvant of treatment by *those psychotherapists who are free* to do so

Such then have been the peculiarly valuable experiences that have fallen to my professional lot I feel looking back, as if I had been for 30 years a professional waste-paper basket And if such a receptacle *is endowed with ears,* eyes and memory even of second or third rate quality it is bound to register some very interesting observations Not the least interesting is the opportunity *of observing* the activities of the fellow or fellows who treated the patient before he was relegated to the waste-paper basket Through these opportunities I have learned much that is admirable of many of my colleagues and of others certain things that make me feel impatient and indignant But of this I am very convinced that the medical men and women who in any capacity treat functional cases lack nothing in heart however limited they may be in head Indeed their compassion is too often exploited by the malingerer and if they appear impatient with anxiety cases it is only because they are unable to understand them.

I would not wish to close the list of my professional opportunities without referring to one which lies on the frontier of psychotherapy I refer to the principles and discipline in child guidance that are associated with parenthood or shall we say [illegible] The matter is not merely of social significance Now that parenthood is becoming almost pathological in its infrequency, the psychotherapist has to deal increasingly with the products of the small family and its implications But he himself has foregone an education to reality which only the cast-iron narcissism of the Victorian era could resist The more I see of modern child guidance the more I see it reverting to those basic principles on which all good nurseries and all happy families have been conducted To have shared in this family experience, whether as child or parent, appears to me to have been a particular privilege for any psychotherapist

The main part of this address, which will appear in full in the *Journal of Medical Psychology*, was devoted to a discussion of neurology, physiology, sociology, philosophy, and religion as frontiers of psychotherapy

OPEN-AIR SCHOOLS

TWO activities of the Save the Children Fund (20, Gordon-square, London, W C 1) mentioned in its seventeenth annual report deserve mention For ten years now the Fund has maintained at Broadstairs an open-air residential school with accommodation for 52 girls, aged from 5 to 15 years They spend three months each at Fairfield House, putting on 6 to 10 lb in weight and doing "just so much school work as is necessary" Of the children 72 have come at the charge of local education authorities but free places have been provided for 87 children from various parts of the home counties It is three years since the Fund began to equip non-residential nursery schools, and seven of these are now running with official recognition from the Board of Education They are located as follows —Tyneside Byker (Newcastle), North Shields, Sunderland, Tees-side Middlesbrough, West Riding Leeds, South Wales Dowlais (Merthyr Tydfil), Brynmawr Recently the schools at Middlesbrough and North Shields have been enlarged, and plans passed for a new school at Hebburn The one school still unrecognised by the Board is at Hoxton, where the school is sound enough but the premises are not up to the mark. The Fund has also given assistance to nine other nursery schools—namely, at Louth, Lincoln, Rochdale, Balham (London), Kentish Town (London), Harrow, Niddrie (Edinburgh), and Methil (Fifeshire) The report records the change in colour of the children from greyish-yellow to the normal pink and brown, and suggests that the children stimulate their mothers to adopt nursery-school standards at home

MUNICIPAL YEAR BOOK.—This valuable year book [1] has undergone several changes in its format since the last edition The directory of national and local authorities which hitherto preceded the general sections now occupies the second part of the book, and this has made necessary some rearrangement in the general sections The book is a faithful chronicle of the developments and achievements of the past year and an encyclopædia of knowledge of local government administration Its appearance this year in January instead of in March is very welcome

CORRIGENDUM.—The reference in a leading article last week (p 274) to a paper by Stamp and Hendry, published in the same issue, should have been to Dr T C Stamp and Mr Edward Hendry, Ph D

ADDRESSES AND ORIGINAL ARTICLES

ANORExIA NERVOSA

WITH SPECIAL REFERENCE TO THE PHYSICAL CONSTITUTION*

BY J H SHELDON M D F R.C.P Lond
HON PHYSICIAN THE ROYAL HOSPITAL, WOLVERHAMPTON AND THE GUEST HOSPITAL, DUDLEY

IT is certainly necessary that diseases should be named, but this entails one disadvantage The title chosen in the first instance is apt to be given on account of a prominent symptom and it directs our clinical appreciation of a case primarily towards this particular feature Unconsciously we tend to regard aspects of the disease which are not suggested by the title as being either derivative or of secondary importance even though they may be as constant as the symptom which happens to give its name to the disease Once a descriptive name has been attached, a channel is provided along which the mind finds it all too easy to flow

Anorexia nervosa is a good instance of this The name itself is a sound one and no complaints are levelled on that score Anorexia is far and away the most prominent symptom and all are agreed that the adjective nervosa is correct in its implication that the origin of the disease lies in the realm of mind The interest of the disease is however by no means limited to those two features In particular the study of five cases under my own care combined with a search of the literature suggests that a proportion of the patients have some degree of pituitary abnormality

Five Case Records

CASE 1 —Miss A aged 18 was seen in consultation on Oct 20th 1935 She had been well until the previous August, after which she had sudden amenorrhœa, menstruation having been previously regular from the age of 12 Shortly afterwards in September 1935 it was noticed that her appetite was failing, and the failure became rapidly progressive until the anorexia was almost total. She was a small girl her height being only 4 ft 10 in and when seen was in a state of severe emaciation the weight being reduced from 6 st to 3 st 13½ lb The breasts relatively escaped and their rounded contour provided a striking contrast to the extreme emaciation of the rest of the body Physical examination was negative except for slight pallor of the discs (cf Fenwick 1880 Case 4) and well-marked hirsuties The limbs and trunk were covered with a dark downy hair while the hair of the axillæ and pubis was abnormally luxuriant The latter tended to stray upwards towards the umbilicus in the masculine distribution. The mother told me that since a child she had been renowned in the family for her hairiness The general picture was very suggestive of anorexia nervosa but the small stature slight pallor of the discs, hirsuties and the fact that amenorrhœa had preceded the anorexia suggested a doubt lest the case might be one of pituitary cachexia and she was accordingly removed to a nursing home for investigation

(1) Radiography of the skull showed a small and shallow pituitary fossa (2) The basal metabolism was greatly depressed An exact estimation was difficult owing to the easy exhaustion of the patient but the readings varied between minus 20 per cent and minus 32 per cent (3) Blood count urine and fæces were normal (4) A blood-sugar curve gave an almost straight line The initial level was 0 106 per cent and the half hourly readings after taking 50 grammes of glucose were 0·103 0·093 0 093 0 112, and 0 11[illegible] per cent Taken with the other clinical features, these findings appeared to support the suggestion of pituitary disease On the other hand the patient s behaviour under observation and her almost complete refusal of food were typical of anorexia nervosa.

She was seen in consultation by a psychologist Dr J Hammond of Wolverhampton who accepted her from his point of view as a typical anorexia nervosa and also by Prof L G Parsons of Birmingham who considered there was sufficient evidence to suggest a diagnosis of Simmonds s disease A decision as to the most suitable line of treatment was not easy but in order not to confuse matters it was decided to initiate psychological treatment only which was carried out by Dr Hammond. On this the patient regained her appetite making a slow but uninterrupted recovery and on discharge from the home at Christmas 1935 she had gained exactly 1 st in weight Since then she has continued in perfect health, and has returned to her old weight of 6 st But though for nearly a year her nutrition has been perfect the amenorrhœa has persisted and her hirsuties and small stature are unchanged

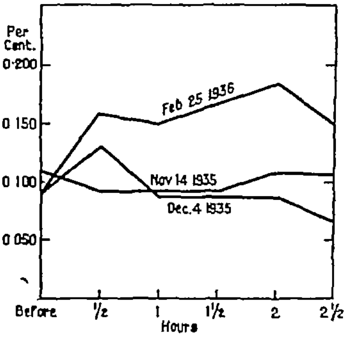

FIG 1.—Blood-sugar curves in Case 1
(Test dose = 50 g. glucose)

Parallel to the improvement in the general condition there was a change in the blood sugar curve On Dec 4th 1935 the starvation level was 0·081 per cent and after 50 g glucose the half hourly readings were 0·131 0 086 0·086 0·086 and 0·068 per cent The curve was therefore still a flat one except for the initial rise On Feb 25th, 1936 the starvation level was 0 086 per cent and after 50 g glucose the half hourly readings were 0 158 0·150 0 168 0 181 and 0·150 per cent These are shown in Fig 1

Here therefore is a case which from its recovery under psychological treatment alone must be regarded as one of anorexia nervosa, but which appears unusual because the anorexia was in a sense an incident in a preceding and still persisting amenorrhœa and also because the patient s small stature small pituitary fossa hirsuties and flat glucose-tolerance curve combined strongly to suggest pituitary disease I now believe that the presence of physical features suggesting an underlying pituitary anomaly is by no means uncommon

CASE 2.—Miss B aged 23 was seen on Nov 25th 193[illegible] through the courtesy of Dr Hammond Menstruation had begun at the age of 16 and after its onset the periods were irregular with 2–3 months interval between them though the loss was normal From the age of 14 she had suffered from periodic headaches lasting a day at a time felt mainly behind the eyes and accompanied by photophobia The anorexia began at the age of 18½ in 1931 and her last period occurred two months before this The anorexia lasted until the middle of 1933, when its true nature being recognised it responded rapidly to psychological treatment During the illness her weight fell to 5 st, but when she was seen by me it had risen to just over 9 st Menstruation returned at Christmas, 1933, some months later than recovery from the anorexia, and then somewhat changed in character, the periods being now quite regular but scanty in amount There was no hirsuties and the growth of hair was normal

---

* Abridged from a lecture delivered to the Osler Society University of Oxford, on Nov [illegible]th 1936

This is a case in which anorexia nervosa developed in a patient whose menstrual functions were somewhat late in appearance, and irregular when established Amenorrhœa preceded the anorexia, but with recovery from the anorexia menstruation has become regular

CASE 3 —Miss C, aged 35, has suffered from anorexia for many years At first her refusal of food appears to have been absolute, but as with many of these cases where neither recovery nor death has occurred, she has now passed into a state of chronic starvation, eating only just enough to keep body and soul together There was severe emaciation in which, however, the breasts did not proportionately share, being rounded and resembling those of a young girl The axillary hair was entirely lacking and the pubic hair was scanty and definitely subnormal in amount for a woman of her age Menstruation had begun at a normal age but from its onset there had been extremely severe dysmenorrhœa, which having resisted all treatment was eventually treated by hysterectomy The uterus was found to be infantile

This is a case of chronic anorexia nervosa in which the dysmenorrhœa associated with an infantile uterus and the maldevelopment of the sexual hair all suggest a constitutional pituitary weakness (It may be added that all attempts to help this patient proved futile, since she declined to leave her home, and was encouraged in this attitude by her mother, and in the relations existing between these two an adequate psychological causation for the anorexia was apparent)

CASE 4 —Woman aged 23 There was a family history of mental disease It appears that shortly before April, 1933, she had become "peckish" and "finicking" about her food, but this had caused no anxiety, and the family did not think that anything was wrong with her until April, 1933, when menstruation ceased Soon afterwards her capricious appetite changed to anorexia, which has persisted and passed into a chronic state of semi starvation, the weight being reduced to 5 st 10 lb No abnormalities were found on physical examination, and the growth of hair was normal Radiography of the skull showed a small pituitary fossa A glucose tolerance test gave a fasting level of 0 66 per cent, with half hourly readings after 50 g of glucose of 0 181, 0 222, 0 200, and 0 181 per cent (I am indebted to Dr G C Sheldon of Reigate for the opportunity of seeing this case)

CASE 5 —Miss D, aged 16, was admitted to the Royal Hospital, Wolverhampton, on Jan 9th, 1936, because of wasting and loss of appetite She was a small under developed girl, whose height was under 5 ft and whose weight was 4 st 2½ lb For some months she had been slowly losing her appetite, and for the last four weeks the anorexia had been almost complete There was no diminution in her daily activities, however, indeed the mother told me that she would manage a whole day's work in the factory (screwing nuts on to bolts) on a small piece of bread for breakfast and a small glass of milk at night With a hospital atmosphere and encouragement from the ward sister the anorexia rapidly ceased, and she began to put on weight but unfortunately before recovery was complete she developed signs of tuberculosis and had to be discharged to a sanatorium Physically infantile, she showed no signs of puberty Menstruation had not begun there was no development of hair either in the axillæ or pubis, and the breasts were only just noticeable Radiography of the skull showed a wide but shallow pituitary fossa B M R =plus 10 4 per cent Blood sugar curve on Jan 10th, 1936, gave a resting level of 0 118 per cent, and after taking 50 g of glucose the half hourly readings were 0 112, 0 118, 0 131, 0 125, and 0 118 per cent —a flat curve like that found in Case 1 On Feb 5th, when her appetite had recovered, the curve was of different type The resting level was 0·086 per cent, and the half hourly readings thereafter were 0 187, 0 200, 0 200, 0 181, and 0 168 per cent These are shown in Fig 2 (I am indebted to Dr S C Dyke, hon pathologist to the Royal Hospital, Wolverhampton, for the laboratory reports in Cases 1 and 5)

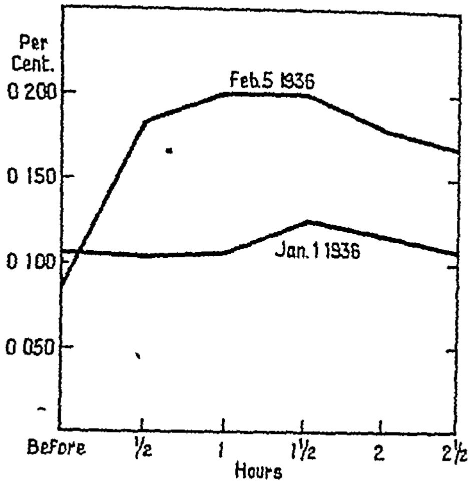

FIG 2.—*Blood-sugar curves in Case 5*

Discussion

Of these five patients, two (1 and 5) showed clear evidence of pituitary dysfunction, while in two others (2 and 3) this was presumptive (irregular menstruation and headaches in one case and an infantile uterus in the other) It is possible therefore that there is a special type of body mind which is peculiarly apt to develop anorexia nervosa in response to emotional difficulty The presence of a constitutional factor is also suggested by the contrast between the extremely clear-cut clinical features and the much more diffuse psychological background. Published records contain a surprising number of observations of the same general import, which may now be discussed in detail

PHYSICAL CHARACTERISTICS

1 *Height* —Two of my patients were under 5 ft in height The literature contains no specific statements on this point, and it is certain that the disease may affect persons of all heights Venables (1930) notes that in two of his patients (males) the height was of the order of 6 ft Lockhart Stephens's patient was 5 ft 4 in Heights are recorded by some of the French authors, especially Noguès (1913), and in nine instances varied between 1 45 m and 1 70 m with an average of 1 60 m (5 ft 2 in) Ryle in his Schorstein lecture (1936) refers to 12 cases Of these one was stated to be "small" and two were described as "diminutive" The available evidence allows of no definite statement, but rather suggests that in this disease there may be a significantly greater proportion of individuals with small stature than in the general population In connexion with growth, there is one remarkable French case which deserves resuscitation

Noguès (Case 13) —A woman who was 24 when she came under the author's care She had begun to men struate at the age of 13 but after two or three months the periods had ceased until the age of 20 The cessation was ascribed to the fact that at the time of onset of the periods she had grown rapidly and it was thought she had exhausted her strength At the age of 20 her height was 1 m. 60 cm In May 1900 (age 20) her periods reappeared and after several days of lassitude and irritability it was noticed that she had suddenly grown. Measurements showed that she had grown 3 cm (a little more than 1 in.) in fifteen days After this rapid growth the periods ceased again the next month Anorexia developed soon afterwards

After a long period of dormancy this sudden activity of both the sex and growth hormones of the anterior pituitary is remarkable and perhaps not less remarkable is the fact that the same patient was afterwards the subject of anorexia nervosa

2 This failure of growth is paralleled in some cases by failure of *sexual development* though it is rare for this to be of the extreme type found in Case 5 Langdon Brown notes that the sufferer is generally under-developed sexually In the male Venables (1930) records a case in a boy of 18 whose sexual development corresponds with that of a boy of 14 or 15 (Case 0) The disease is rare in males and this is the only apposite instance I have been able to find in the literature There is abundant evidence however that many of the female cases have a sexual development below normal.

The age of onset of menstruation appears usually to be normal, but it is sometimes retarded. In 12 instances the extremes of age were 12½ years and 17 years (2 cases) with an average of nearly 14 years There are in addition a number of cases where menstruation had never occurred at the time of the disease These are as follows —

Author	Recorded age	Author	Recorded age
Noguès (3)	15	Noguès (7)	18
Gull (3)	15 8/12	Levi (3)	18
Noguès (8)	10	Noguès (16)	24

(No of case in parentheses)

These numbers are not large in themselves, but they are drawn from a total of only 45 case reports and therefore represent some 12 per cent of the total. A further feature of some cases is that the periods have appeared at a normal age but have only lasted for 2 or 3 months and have then ceased They are as follows :—

Case.	Recorded age	Age of onset of menstruation.	No of periods.
Noguès (11)	17	13	2 or 3
Noguès (13)	4	13	2
Comby (1)	13½	1	5
Denlau (1)	1	11	

The evidence suggests therefore that in a proportion of the cases of this disease there is a significant delay—or weakness—in the sexual development of puberty The presence of general infantilism and of an infantile uterus in my two cases is in keeping with this

3 The literature provides several instances in which before the anorexia the patient has been unusually stout Ryle states that *slimming on account of adolescent plumpness* is generally considered to be the second in importance of the psychological causes Some of the records suggest that this plumpness might at times justify the term obesity

(*a*) Thus J C. Young reports of a case in a woman of 2[illegible] that "the patient became very plump about the time of puberty (possibly a pituitary disturbance) She evidently was very fat for the stepmother accused her of pregnancy and had her examined by a doctor

(*b*) Noguès (Case 5) reports the case of a girl of 19 who while at boarding-school from the age of 11 to 16 weighed 60 kg (9½ st) and was so teased on the subject by her friends that she ultimately developed anorexia nervosa.

(*c*) Noguès (Case 6)—This was a woman of 20 who was big and fat in childhood At the age of 19 she attended a wedding where her friends made a point of teasing her at being easily the biggest person at the function (an incident which led directly to the development of anorexia nervosa)

(*d*) Noguès (Case 12)—This was a girl of 18 who was always a big fat child At the age of 15½ she weighed 9¼ st (59 kg) She remained quite indifferent to the teasing of her school friends until one day her aunt remarked that if she went on like that she would become as big as her mother a prospect which so appalled her that she started slimming which led to true anorexia nervosa

(*e*) Comby (Case 1)—Reports the case of a girl who at the age of 13½ was 5 ft 4 in. high and was a very big girl."

(*f*) Ryle reports two instances in his series In one a girl of 19 had been told she was too fat and in the other a girl of 17 the doctor reported that before the illness she had been very stout "

It is clear that in certain cases not only has adolescence been plump but that its degree has left an impression on the minds of both medical and lay observers of the patient. Although it is the psychological effect of this obesity which leads to the anorexia yet the implication of a mild pubertal derangement of pituitary function accords well with the other evidence pointing in the same direction

4 One of my cases had marked *hirsuties* This feature of the disease has been emphasised by Ryle who states the physical stigmata of anorexia nervosa include an overgrowth of downy hair on the trunk and limbs and that in cases of longer standing there may be coarser hairs on the chin Birley (1033) notes that female cases show a tendency towards a male distribution of hair while the reverse *may be found in males Many have noticed that* as a result of the starvation the hair tends to be dry and in one case (Nogues) there was even a slight alopecia which cleared up when the anorexia ceased. Of the five cases above one had general hirsuties with overgrowth of the sexual hair One had no sexual hair at all (age 10) but was otherwise normal in this respect One patient (age 35) had well marked weakness of sexual hair (armpits and pubis). Two patients were normal.

It is clear that in a proportion of the cases the condition of anorexia nervosa has developed in individuals possessing a characteristic collection of physical stigmata In one way or another these agree in their implication of a disturbed pituitary function particularly apt to be seen at puberty It may again be emphasised that although a liability to one type or another of pituitary anomaly appears to form part of the physical constitution of anorexia nervosa the immediate causation is undoubtedly psychological. If there be such a physical constitution at any rate in the large group of cases occurring between the ages of roughly 15 and 25 the amenorrhœa as well as certain other features (low basal metabolism and alterations in sugar tolerance) acquire a new interest

FUNCTIONAL DISTURBANCE

1 *Amenorrhœa* is one of the cardinal features of the disease and its mechanism has not received the attention it deserves largely because attention has been so closely focused on the appetite The amenorrhœa is usually stated to result from the anorexia and this possibility is borne out by the record of famine which causes early loss of menstruation

In a description of the Indian famine of 1879, Cornish writes —

> "There was an impairment or abolition of the menstrual function The secretion was scanty and irregular in the younger women it had ceased prematurely in those of more advanced years, and in many instances of emaciation in younger women the function had temporarily ceased It was also observed that in young girls puberty was retarded The wasting of the mammæ was a very prominent feature in starving women in the worst cases this was so absolute that the gland appeared to have completely disappeared"

It should be noted in connexion with the last point that the reverse is often found in anorexia nervosa This was very evident in Case 1, and the escape of the mammæ from the general wasting was noted by Lockhart Stephens in 1895 (See also Noguès, Case 8) though the opposite is sometimes found (cf Clow, Case 2) Birley states that in one male case there was a mammary hypertrophy

The state of affairs in famine therefore supports the view that the amenorrhœa of this disease may be secondary to the anorexia A study of the clinical records, however, shows that it is often an independent and parallel symptom This is the point of view adopted by Ryle In cases where the amenorrhœa develops after the anorexia, it is indeed likely to be the result of the starvation, but there is abundant evidence that it may also develop either before the anorexia or at the same time Ross (1931) states "from our histories we have failed to find an explanation of the amenorrhœa. Sometimes the menses have never been established satisfactorily, sometimes there had been regular periods The stoppage does not seem to be the result of the emaciation, as it has occurred sometimes before there was any great loss of weight" In my first two cases the amenorrhœa preceded the anorexia Most of the case reports in the literature are not very clear as to the exact time relation between these two symptoms, but in those of Comby, of Noguès, and of Ryle the amenorrhœa appears to have antedated the anorexia Ross reports the case of a girl of 19 A few months before the anorexia appeared she had a period of mild exhaustion, during which the menses stopped Shortly after this she left home for college, and six weeks later she presented the symptoms of complete lack of appetite, amenorrhœa, and irritability of temper There are numerous cases on record in which both symptoms appear to have arisen together (cf Noguès, Cases 4 and 9, Comby, Cases 2, 3, and 4, Sollier, Case 1, Deniau, Case 1), while there are others in which the amenorrhœa was definitely secondary

Clow (1)	Anorexia	3	years	before the	*amenorrhœa*
Berkmann (1)	"	4	months	"	"
Noguès (6)	"	10	"	"	"

It is clear therefore that in not all cases can the amenorrhœa be regarded as secondary to starvation. It cannot be regarded as the cause of the anorexia, and the most reasonable explanation is that it is an hysterical or functional symptom that develops independently of, but parallel to, the anorexia Amenorrhœa of purely emotional origin is well known, and no purpose would be served by detailing further case histories The mechanism of this type of amenorrhœa, if it were known, would undoubtedly be of great interest and would repay study with the modern methods at our disposal. The importance of this view lies in the fact that unlike the anorexia, failure of menstruation involves a physical mediation of which the pituitary is part The observations detailed above, which suggest that in some cases at any rate the functions of the anterior pituitary are already subnormal, are obviously relevant to this

2 *Basal metabolism*—A lowered basal metabolism is a common feature of anorexia nervosa, and indeed it has been erroneously suggested on the strength of it that thyroid provides the most suitable treatment Of the cases above in which it was measured the figures were −20 per cent and −32 per cent in one case and +10 4 per cent in the other In Venables's second case the basal metabolism was said to have been "low" Birley (1933,) found a value of −43 per cent, while in Wittkower's case it fell to −76 per cent

Berkmann reports an extensive series of cases as follows —

No of cases	B M R	No of cases	B M R
13	0 to −10 %	21	−30 to −40 %
34	−10 to −20 %	2	Over −40 %
46	−20 to −30 %		

He suggests that the depression of the metabolism is a protective mechanism, since a person with a low metabolic rate requires less nourishment than the normal person, and that without the lowered metabolism death would occur more often and more rapidly than it actually does This, however, takes no account of the extreme degree of mental and bodily activity often exhibited by these patients, which has received its classical description from the pen of the late Sir Clifford Allbutt The mechanism of this lowering of metabolism is obscure It bears no relation, apparently, to that of myxœdema, and it is not to be taken as an indication for the use of thyroid A similar lowering of the basal metabolism is a constant feature of Simmonds's disease

3 The *glucose tolerance* curves described above depart markedly from the standard curves of the text-books, and until recently they would undoubtedly have been regarded as indicating a disturbance of pituitary function They tend to be of two types (*a*) There is the initial curve displayed by Patients 1 and 5, both of whom were small and had other evidence of pituitary dysfunction These curves were distinguished by the fact that after the ingestion of 50 g of glucose there was no rise in blood-sugar or a rise of only the most modest dimensions, and they suggest either a failure of absorption or an excess production of insulin resulting in a great increase of carbohydrate tolerance (*b*) In the course of treatment these curves altered in each case in the same direction, the curves tending towards the diabetic type Case 4 had also a curve of this type, an initial figure of 0 66 per cent rising to 0 222 per cent in one hour and falling only to 0 181 in two hours These curves, however, hardly fall outside those described by Himsworth (1935) as occurring in normal people after a period of abnormal diet If they are to be explained on this basis it has to be assumed that Patients 1 and 5 before coming under observation had both been living on a diet rich in carbohydrate, which had greatly increased the factor of insulin sensitivity, while the progress under treatment to the opposite type of curve was due to their taking a diet rich in fat Unfortunately I cannot offer accurate information on this point, since it was extremely hard to discover exactly what these patients were eating before coming under observation, but it is my impression that this is not the explanation This aspect of the disease is certainly worthy of more detailed study in future cases, for the well known participation of the pituitary in carbohydrate metabolism and the disturbance of this metabolism described in Simmonds's disease

suggest an alternative avenue of causation The three features (amenorrhœa low basal metabolism and disturbance of carbohydrate metabolism) all form part of the syndrome of this disease and it is also characterised by an extreme loss of weight sometimes accompanied by anorexia The resemblance to anorexia nervosa is obvious and it is unfortunate that the differential diagnosis between them has not occupied more attention from those who have described the syndrome of pituitary cachexia. That this is pertinent may be illustrated from the *difficulty in diagnosis offered by my first* case and while this is no doubt unusual it is probable that such cases occur more frequently than is generally recognised. It may also be illustrated from the case of Simmonds's disease described by Hawkinson (1935) which, apart from the stress laid on the fall of hair somnolence and ageing would do quite well for a characteristic anorexia nervosa—and may actually have been that This patient, a girl of 17 had severe anorexia (half a glass of milk daily) loss of weight (50 lb in 5½ months), amenorrhœa and low basal metabolism Her appetite rapidly returned on treatment with anterior pituitary like gonadotropic principle of pregnancy urine (Follutein) and eventually she progressed to recovery It would be of interest to know how an undoubted instance of anorexia nervosa would respond to such treatment both as regards appetite and menstruation It almost appears as if a similar mechanism were concerned in both types of disease but actuated by a psychological factor in one and by physical means (infarction, &c) in the other (A preliminary survey has, indeed already shown that many of the cases ostensibly described as Simmonds's disease particularly in early life are clinically indistinguishable *from* anorexia nervosa This matter will be dealt with later)

Summary and Conclusions

In laying emphasis on physical aspects of anorexia nervosa which suggest that in some cases there is an underlying hypofunction of the anterior pituitary I do not in any way desire to amend the current conception of the disease—that the loss of appetite begins in response to some psychological need and once established is perpetuated as an hysterical condition This conception is borne out by the fact that physical treatment for the anorexia is out of place the patients being able to recover their appetite with suitable psychological help alone A common emotional cause will explain both the anorexia and the amenorrhœa often associated with it But in the chain of events which lead to the amenorrhœa the pituitary must be involved, and it is of great interest that there is often evidence that the functions of this gland are already subnormal The deficiency may show itself by small height delayed onset of puberty infantile uterus adolescent obesity and in other ways The number of cases in which such observations have been made is impressive but it is clear that they only represent a portion of the whole and they belong almost entirely to the group of cases occurring between the ages of 15 and 25 (Of 57 cases on record 18 showed such features so that about a third of the cases of anorexia nervosa appear to be of similar constitutional tendency) Indeed the symptoms of anorexia nervosa—loss of appetite and weight amenorrhœa low basal metabolism and alterations in carbohydrate metabolism are so similar to those of Simmonds's disease as to suggest that at any rate in the group of cases with which this paper is concerned we are really dealing with a functional Simmonds's disease—a pituitary black-out of psychological origin It is possible that only a certain type of body mind reacts in this particular way that the infantility which often characterises the psychological background may be the counterpart of an actual endocrine infantility This recalls the well known saying of Galen no cause can become efficient without an aptitude of the body and it is to be hoped that the observations collected in this paper may be extended over a longer series of cases for it appears to be a promising field *not only for the study of constitution* but of the more ultimate mysteries involved in the mind body relation

INTRANUCLEAR INCLUSIONS IN THE EPITHELIUM OF THE HUMAN MALE GENITAL TRACT

By J R Gilmour, M R C.P Lond
GROCERS' RESEARCH SCHOLAR
(*From the Bernhard Baron Institute the London Hospital*)

(WITH ILLUSTRATIONS ON PLATE)

In the course of routine examinations of specimens from the operating theatres I observed intranuclear inclusions in the epithelium of the tract developed from the Wolffian duct I therefore examined systematically the microscopic sections from this tract that are reserved in the cabinets of the Bernhard Baron Institute supplementing these with material from current necropsies Later I found that these inclusions had been described and figured by Hammar (1897) as granules in the nuclei of the canal of the epididymis of dogs His findings are referred to later

CHARACTER OF INCLUSIONS

The inclusions (Figures on Plate) are round and of dense homogeneous structure and are stained deeply with eosin As a rule they are closely bounded by a *delicate capsule of chromatin Sometimes however* they lie free in the nucleoplasm without any chromatin capsule and occasionally especially when large they are separated partially or completely from the chromatin capsule by a clear crescent or ring Sometimes it appears as if fragmentation of a large inclusion has formed numerous small spherical or granular examples within a single capsule The number within a nucleus varies considerably usually there is only one but there may be as many as six One large or several small inclusions may distend a nucleus conspicuously One or more nucleoli may be seen in a nucleus as well as inclusions It is impossible, however, to decide whether the inclusions are or are not derived from nucleoli The nuclei and the bodies of the cells containing inclusions show no definite signs of degeneration or special activity

The inclusions can be recognised when 1 micron in diameter and varieties up to 7 micra occur, the usual size being between 3 and 5 micra They are often clearly visible under a ⅓ in and always under a ⅙ in objective, but a 1/12 in objective is very useful when they are small and scanty, as is especially the case about the time of puberty

SITE AND DISTRIBUTION IN TRACT

The inclusions were found in the canal of the epididymis, throughout the vas deferens, and in the seminal vesicles and common ejaculatory duct The number of examinations of these structures and the results are given in the accompanying Table Many examinations were made of the vasa efferentia, but here the inclusions were never seen Further, no inclusions were found in many examinations of the epoophoron of adult females The inclusions were, therefore, found only in that part of the male genital tract that is derived from the Wolffian duct This part of the male genital tract is lined with two layers of cells In the canal of the epididymis the two layers are best developed, while in the ampulla of the vas deferens and in the seminal vesicles they cannot always be distinguished The inclusions occur only in the columnar cells bordering the lumen, and never in the small polygonal or irregular basal cells

Age	No of subjects	—	Testis	Canal of epididymis	Vas deferens				Seminal vesicle	Common ejaculatory duct.
					Lower end	Cord	Intra-abdominal	Ampulla.		
Birth to 14 years.	34	No of exams	29	32		10			2	
		Spg in—	1*							
		Inclusions in—		1*		0			0	
15 to 80 years	71	No of exams	10	35	14	52	5	9	4	1
		Spg in—	10							
		Inclusions in—		35	14	48	3	3	1	1

* Male 4 years 10 months Macrogenitosomia præcox
Spg = spermatogenesis

In the nuclei of the columnar cells and also of the basal cells an inclusion like structure very frequently occurs, which must not be confused with the inclusions described above They are vacuolar structures bounded by a chromatin capsule The vacuoles are usually clear but occasionally contain a pale eosinophil coagulum They show considerable variation in size They occur not only in the epithelium of the tract derived from the Wolffian duct but in the surrounding muscle cells and fibrocytes, and also in the epithelium of the vasa efferentia and the cells of their walls

RELATIVE AFFECTION OF DIFFERENT PARTS OF THE TRACT

It is not possible to judge accurately the relative frequency with which different parts of the tract are affected, and the relative number of inclusions in the different parts, because of the variation in the amount of the available material, there is a great difference in the number of specimens that were taken from different parts of the tract (see Table), and also in the number of sections of the lumen that are obtained in preparations from different parts The canal of the epididymis is the best site for finding inclusions because many sections of the lumen are present in any preparation Only scattered cells are affected, and in a preparation containing many lumina of the canal of the epididymis all lumina may not contain inclusions It is obvious, therefore, that a negative finding in a single cross section of the vas deferens is not sufficient to exclude their presence It can, however, be stated that there are relatively few in the seminal vesicles and upper part of the vas deferens, and many in the lower part of the vas and in the canal of the epididymis

RELATION TO SEXUAL DEVELOPMENT

Much of the material was obtained from tissue removed in the operating theatres, consequently local disease was present in several specimens Such disease was, however, very variable in character and extent Further, the columnar epithelium was affected in an identical manner in healthy material from necropsies Local disease appears, therefore, to have no influence upon the incidence of the inclusions There is, however, a striking relation to the sexual development of the subject and consequently the age

It will be seen from the Table that the inclusions without exception were not seen before the onset of spermatogenesis, and with one exception were not seen before the age of fifteen In 34 subjects of ages ranging from birth to fourteen years the seminal vesicles were examined microscopically twice, the vas deferens in the spermatic cord 10 times, the canal of the epididymis 32 times, and the testicles 29 times Spermatogenesis was present only once, and in this case alone were inclusions found (Figure on right of Plate) This case has been described fully by Le Marquand and Russell (1934–35) The patient, aged 4 years and 10 months, died of heart failure, fatty degeneration of the myocardium, and rheumatic myo , peri , and endo-carditis Macrogenitosomia præcox was present in association with a small tumour like mass of ectopic brain tissue dependent from the floor of the third ventricle of the brain

In 71 subjects of fifteen years and over the inclusions were found in all in one or other but not all parts of the tract in question Inclusions were found in 1 of 4 seminal vesicles examined microscopically, in the only common ejaculatory duct examined, in 3 of 9 ampullæ of the vas deferens, in 3 of 5 examinations of the remainder of the intra abdominal vas deferens, in 48 of 52 vasa deferentia within the spermatic cord, in all of 14 lowermost ends of the vas deferens, and in all of 35 examinations of the canal of the epididymis The testicles were examined in 10 subjects, of whom 7 were between fifteen and twenty years of age, and spermatogenesis was present in all

Between the ages of fifteen and twenty five the inclusions were fewer than in later years, and at fifteen and sixteen years they were so sparse as to be difficult to find No regular increase with age after twenty five was seen, although the subjects in whom they were numerous and conspicuous were usually in later adult life The number and size of the inclusions varied, indeed, in different subjects of about the same age

NATURE OF THE INCLUSIONS

The inclusions closely resemble morphologically intranuclear inclusions found in proven virus infections. They only differ in being less frequently separated from the chromatin capsule by a clear halo. They resemble the inclusions of Type B of Cowdry (1934) more closely than those of his Type A. They only appear, however, when spermatogenesis is active and are then, according to this investigation, found in all subjects. This makes it somewhat difficult, though not impossible, to accept them as evidence of a virus infection. It is possible that they arise under the influence of a hormone during the period of sexual activity and are expressions of an augmented secretory activity on the part of the cells lining the tract derived from the Wolffian duct. By ordinary histological methods, however, such activity is not apparent.

Hammar in 1897, in a paper upon the secretory appearances in the epididymis of the dog, described and illustrated very fully identical structures in the cylindrical cells of the canal of the epididymis. In the uppermost part of the canal nearly all the nuclei were affected. He did not find them in the vasa efferentia, the basal cells of the canal of the epididymis or in the vas deferens. He found them in all dogs examined from the age of eight months to sixteen years but failed to find them in two foxes. He believed that these intranuclear granules passed into the cytoplasm leaving vacuoles in the nuclei. He concluded that they did not form the cytoplasmic secretory granules that he also described in the epithelium, chiefly because similar cytoplasmic secretory granules were present in abundance in the foxes but no intranuclear granules. He found it impossible to exclude the possibility of their being granules of an internal secretion secreted through the bases of the cells but came to no definite conclusion concerning their nature.

Evidence of the passage of the inclusions from the nuclei into the cytoplasm was not found in the human material examined by me. The vacuoles seen in the nuclei of the columnar cells of the canal of the epididymis were similar to those in the basal cells and the cells of the vasa efferentia, in which the intranuclear inclusions were never found. The inclusions remained in the nucleus even of cells desquamated into the lumen.

Wagner (1930) described in an infant of two weeks protozoa-like structures in the nucleus of cells of many organs including the epididymis and salivary glands. This probably was an example of a virus infection of the type described by von Glahn and Pappenheimer (1925) and by Farber and Wolbach (1932) in which inclusions are found in the salivary glands and other organs of infants.

SUMMARY

In a series of microscopic sections of the male genital tract of man intranuclear inclusions were found in the columnar cells lining the part derived from the Wolffian duct—that is, in the part beginning with the canal of the epididymis and ending in the common ejaculatory duct. Their relative number in different parts of this tract is described. They were not found in the vasa efferentia nor in the epoophoron of the female. They were present in all subjects in whom spermatogenesis was proved by microscopic section or could be inferred from the age. They were not present in subjects under fifteen years of age except in a boy of four years and ten months who showed macrogenitosomia præcox and active spermatogenesis. In morphology they resemble closely intranuclear inclusions in proven virus infections, but their invariable presence when spermatogenesis is active makes it somewhat difficult to regard them as due to a virus infection. To determine their nature experiment is necessary.

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR

A NEW PRINCIPLE OF WIRE INTRODUCTION FOR SMITH-PETERSEN NAIL

BY E. T. BAILEY, M.B. Lond., F.R.C.S. Eng.
SENIOR ASSISTANT MEDICAL OFFICER TO ST. LEONARD'S HOSPITAL, LONDON COUNTY COUNCIL

(WITH ILLUSTRATIONS ON PLATE)

THE insertion of a Smith-Petersen nail without open exposure of the hip joint has been the subject of considerable work, first by Sven Johannson (1934) and later by others, including Lloyd (1935), Brittain (1936) and Hey Groves (1936). These surgeons have introduced techniques dependent upon radiography in two planes with careful measurements and calculations evolved from these.

The method now described aims at the accurate introduction of a Smith-Petersen nail over a Kirschner wire in a manner which obviates the *necessity either for such calculations or for a lateral* X ray during operation. It is based upon the following two anatomical facts. First, the anterior surface of the neck of the femur is a comparatively flat plane extending on to the anterior surface of the shaft immediately below the great trochanter. Secondly, a line through the centre of the neck passes ½ in. behind this plane and emerges from the outer surface of the femur ½ in. below the lower border of the great trochanter, under cover of the origin of the vastus externus muscle.

THE INSTRUMENT

By means of the introducer shown in Fig. I a Kirschner wire is drilled in the axis of the neck and passes automatically ½ in. behind its anterior surface.

The instrument consists of two parts (see Fig. I). (1) A handle carrying a blade (A) ½ in. wide which rests on the anterior surface of the neck. (2) A block (B) reversible for right or left hip attached to the blade 2 in. *from* its point. This block (which is 1 in. square and 2½ in. long) has the inner extremity shaped to the outer surface of the femur at an oblique angle in such a way that when it is brought into apposition with the bone the surface blade (A) lies over the centre of the neck (Fig. II). Through the centre of the block passes a guide hole which directs a known length (3½ in.) of wire into the neck, ½ in. behind and parallel to the surface blade, ready for radiographic confirmation of length and direction, before finally introducing a Smith-Petersen nail over the wire. Two accessory guide holes also pass through the block ½ in. above and below the centre.

METHOD OF INTRODUCTION

An injection of Omnopon gr. ½ and scopolamine gr. 1/100 is given, followed by a spinal anæsthetic of

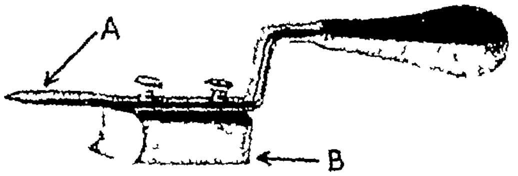

FIG I —The introducer (A) blade (B) block with central and accessory guide holes

3 c cm Decicain, and the patient is turned half over on to the sound side

An incision 3 in long is made along the line of the femur commencing over the middle of the great trochanter The skin and fascia lata are divided and the vastus externus exposed The fibres of this muscle are divided longitudinally and the bone bared for 1 in immediately below the lower border of the great trochanter The blade of the introducer is inserted along the anterior surface of the neck keeping well on to the bone, until the block is brought into apposition with the shaft of the femur in the space cleared The block is felt to "lock" against the side of the bone and is pressed upwards to ensure that it is immediately below the trochanteric attachment of the vastus externus which will prevent it from riding any higher on the bone The blade should now lie over the centre of the neck and may be checked by feeling for the lower end of the intertrochanteric ridge at the angle of the neck, which should be one finger's breadth below the blade An assistant then holds the introducer in position while 6 in of Kirschner wire are drilled through the centre guide hole, leaving 2½ in in the block and 3½ in in the neck The introducer is withdrawn leaving the wire in position, and a radiogram is next taken in the antero posterior plane for estimation of the length of Smith-Petersen nail required, and for confirmation of position No attempt is made to take a lateral view, the correct depth being assured, but the antero posterior view shows whether or not the wire is centrally placed from above downwards In the majority of cases the wire is found to be in a mid position Should, however this be a fraction too high or too low, the introducer is replaced over the wire, and a second wire is inserted through the appropriate accessory guide hole parallel to the first, which is withdrawn The Smith Petersen nail (Sven Johannson type) is then guided over the wire and impacted into the neck The wire is then withdrawn as soon as the nail has entered for 2 in The edges of the vastus externus are brought together over the head of the nail and the skin wound is sutured The procedure takes 15–20 min with 10 min for the taking and developing of the radiogram (see Figure on Plate)

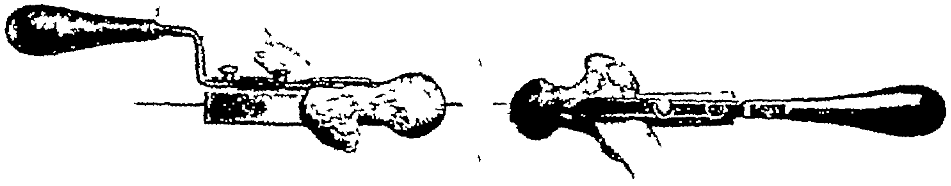

FIG II.—Left the introducer in position, from above showing the wire passing through the block and the centre of the neck of the femur ¼ in behind the blade Right the blade resting on the anterior surface of the neck

The above method was given repeated satisfactory trials on the cadaver before engaging on a current series of clinical cases These cases are all treated in the first instance by a "strapping" extension applied as soon as possible after the accident to the limb which is slung in a Thomas's splint Weights varying from 16 to 30 lb are applied until reduction is affected as shown by radiography in two planes The extension gives immediate relief from pain, and assists in the improvement of the general condition, which on an average permits of the insertion of a nail in 10–14 days after the accident The spinal anæsthetic and introduction of the nail are carried out without moving the patient from bed, or disturbing the weight extension, and the radiogram is taken with a portable machine, with the cassette placed under the patient before the operation is begun

This complete "bed procedure" is strongly advocated, but the method is equally applicable to the more common usage of traction combined with an orthopædic table, and of other forms of anæsthesia, such as local, nitrous oxide and oxygen, or intravenous, should these be preferred

I am indebted to Dr A Morris, medical superintendent of St Leonard's Hospital, for the facilities that he has given me, to the hospital staff for their coöperation, to Mr A D Brown for his careful radiography and photographic illustrations, and to Surgical Equipment Ltd., North Acton, for their efficient manufacture of the introducer for the London County Council

(WITH ILLUSTRATIONS ON PLATE)

THE use of thorotrast as a means of visualising the cerebral circulation was introduced by Moniz (1931) as a substitute for sodium iodide This practice has been adopted in many neurosurgical clinics and has proved to be a valuable auxiliary method of diagnosis After three years experience Moniz (1934) emphasises the harmlessness of thorotrast He finds no radiological evidence of its retention in the cerebral vessels but no histological studies appear to have been made either by Moniz or others to settle this point.

The possibility that a pathological lesion might alter the fate of the thorotrast has been considered by Alexander Jung and Lyman (1934) who think it unlikely that in the presence of an intracranial vascular lesion the thorium dioxide would reach the parenchyma since the lesion would be in an area of stasis. The colloidal thorium dioxide could hardly be expected to penetrate this area of stasis but would be carried off at once in the actively flowing stream of blood into which it is injected. In this paper we are not concerned with the main sites of storage in the body but only with the evidence of its retention in the brain in certain intracranial diseases. In the first four of the following cases thorotrast has been detected in the brain at varying intervals after its injection.

Case I

Male, aged 55 years. Old cerebral hæmorrhage Degeneration of cerebral and systemic arteries Arteriography

CLINICAL HISTORY

He had suffered from indefinite headache since childhood Whilst out walking on Dec 1st 1935 he noticed that his left eye was "cold and felt dead." He returned home to bed and during the evening he had a generalised convulsion with loss of consciousness lasting half an hour On the following day his speech was noticed to be affected, and this trouble together with "coldness" and failure of vision in the left eye steadily increased and was associated with more pronounced frontal headache On Jan. 21st 1936 physical examination revealed very slight bilateral papilloedema, retinal arterio sclerosis a small retinal hæmorrhage and an almost complete right homonymous hemianopia There was slight right facial weakness of an upper neurone type with diminution of the abdominal reflexes on the right side Aphasia was severe and affected both afferent and efferent pathways and there was alexia and agraphia. Cerebro spinal fluid: 6 white cells per c.mm., total protein 120 mg per 100 c cm Blood pressure 195/130 mm. Hg Wassermann reaction in blood and cerebro-spinal fluid negative Radiograms of the skull gave no helpful information

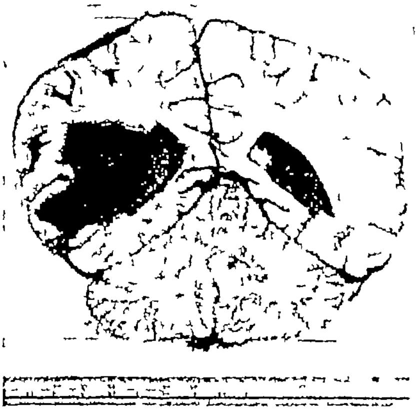

FIG 1 (Case I) —Coronal section of brain to show hæmorrhage in left hemisphere.

The lesion was clearly situated in the left temporo occipital region and arteriography was performed in order to distinguish between cerebral vascular disease and a rapidly growing glioma On Jan 22nd 1936 both common carotid arteries were exposed under local anæsthesia the patient having received 3 grains of Nembutal by mouth as a sedative; as he became uncontrollably restless more nembutal was given intravenously Thorotrast (10 c cm.) was then injected into each carotid artery in turn. The radiograms demonstrated gross dilatation of both carotid siphons In addition, on the left side the posterior part of the Sylvian group of blood vessels and the pericallosal artery were considerably displaced upwards and forwards suggesting a large left temporo-occipital tumour

The patient never regained consciousness; the temperature pulse and respirations rose rapidly and he died with signs of pulmonary œdema and heart failure on the following day 21 hours after the injection

MACROSCOPIC EXAMINATION (P M 30/1936)

A hæmorrhage (6 by 4 by 3.5 cm.) occupied the white matter of the left cerebral hemisphere lying deep to the terminal part of the Sylvian fissure close to the middle cerebral artery and extending posteriorly beneath the superior temporal convolution to end in the occipital lobe over the dorso-lateral aspect of the occipital horn (Fig I)

---

* Working for the Medical Research Council.

In many places the clot was brown and pultaceous The surrounding white matter frequently showed cystic or gelatinous softening with conspicuous orange brown pigmentation There was no evidence of recent hæmorrhage No aneurysm was found on dissection of the blood vessels, the hæmorrhage appeared to be due to leakage from a branch of the left middle cerebral artery which, in common with the other main cerebral arteries, was greatly dilated and showed severe atheroma

There was severe fibrosis of the myocardium secondary to coronary atheroma, but no definite myocardial hypertrophy (Weight of heart 13½ oz)

MICROSCOPIC EXAMINATION

Paraffin sections of tissue from four different parts of the periphery of the hæmorrhage were examined Two of these included the adjacent left middle cerebral artery, one was from the anterior end of the hæmorrhage, and the fourth included the posterior end of the hæmorrhage and the adjacent wall of the occipital horn

In all parts the hæmorrhage is enclosed by a broad inflammatory zone in which the nervous tissue is densely infiltrated with lymphocytes, polymorphonuclear leucocytes, and macrophages containing iron pigment Many of the capillaries and small veins throughout this zone, as well as in the more remote cortex and white matter to a distance of 1 5 cm, are dilated and plugged with a highly refractile, homogeneous hæmatoxyphil substance (Figs II and III on Plate) The plugs are purplish red in Weigert's iron hæmatoxylin and van Gieson, and are negative to stains for fibrin and iron As a rule they are slightly retracted from the endothelium and, in many places, are broken up into droplets of various sizes amongst which are found red corpuscles Unstained brightly refractile particles, identical in appearance with those found in the Kupffer cells of the liver in this and in other cases where thorotrast has been injected, can be seen with a 1/12 inch objective to adhere in places to the endothelial lining of the vessel The cytoplasm of the endothelial cells of the affected vessels is occasionally vacuolated No particles are present outside the walls of any vessels that lie beyond the inflammatory zone In the latter, however, the particles have in some instances penetrated the vessel wall They are then seen both in the cytoplasm of the endothelial cells and also packed within adventitial macrophages In such situations they are distinguished from the granules of iron pigment by their greater refractility, but above all by their lack of colour, their negative reaction to Turnbull's blue (Mallory's modification) No occluded vessels were found in the leptomeninges

Distant parts of the brain in this case were unfortunately not examined

COMMENT

In this case in which death followed 21 hours after the injection of thorotrast, there is histological evidence of extensive occlusion of small veins and capillaries by a substance of colloidal appearance which we interpreted as thorotrast To obtain confirmation of this we injected thorotrast through the renal artery into a kidney at necropsy Sections, cut and stained in the same way as the pathological material, showed obstruction of the vessels by material of identical appearance and staining properties Additional proof of the identity of the colloidal material was given by the presence at the periphery of the plugs and, in some places, within the adjacent endothelium and adventitial macrophages of numerous highly refractile, unstained particles, resembling those found by us and others in the Kupffer cells of the liver after the injection of thorotrast

A greater degree of permeability of the capillaries in the inflammatory zone in comparison with those in the remoter brain tissue is shown by the passage of thorium dioxide beyond the confines of the vessel walls This increase of permeability of the cerebral capillaries in inflammation is well recognised and has been discussed at some length by Burrows (1932)

Case II

Female, aged 41 years Meningioma of falx. Arteriography and subsequent operative removal of tumour with adjacent cerebrum

CLINICAL HISTORY

She had suffered for two years from progressive weakness of the right leg later involving the right arm More recently there had been headaches, with increasing disturbance of speech and memory She was a right handed well nourished woman, with marked loss of memory and concentration, and with a considerable degree of expressive aphasia There was blurring of the right optic disc, and a right homonymous hemianopia She had a fairly pronounced right hemiparesis with which was associated gross sensory loss of a cortical type Radiograms of the skull gave no information of localising value The blood pressure was 118/90 mm Hg The cerebro spinal fluid was normal On August 10th, 1936, arteriography was performed under local anæsthesia 15 c cm of thorotrast being injected into each common carotid artery On the left side the arteriogram showed in the frontoparietal region the faint outline of a tumour causing a marke depression of the pericallosal and callosomarginal arteries The diagnosis was made of a falx meningioma in this situation.

Immediately after the thorotrast injection the patient became unconscious and remained so until her operation. In addition the hemiparesis appeared to become absolute These manifestations were assumed at the time to be due to some vascular disturbance created by the injection On August 12th, 1936, the tumour was exposed by excising a piece of frontal lobe anterior to the precentral gyrus (identified by thyratrone stimulation), and was completely removed About two thirds of the tumour lay in the frontal lobe anterior to the Rolandic sulcus the posterior third occupying the parietal lobule

The patient made a satisfactory recovery from the operation as regards her general physical state, swallowing and mental alertness For some weeks there was no recovery from the hemiplegia, and speech was limited to 'Yes" and "No" Her powers of understanding however wer evidently fairly acute On Sept 5th she was transferre to a nursing home During the last few days before leaving hospital slight power returned in the leg and arm and increased slowly, so that when last seen on Nov 13th, 1936, she was able to walk unaided, and could carry on a reasonable conversation

PATHOLOGICAL EXAMINATION (S D 2046/1936)

The material received for histological examination consisted of numerous fragments of tumour, together measuring 8 cm in diameter and up to 1 cm high Microscopic examination confirmed the clinical diagnosis of meningioma of the falx The blood vessels of the tumour contained no abnormal material Accompanying the tumour was the portion of frontal lobe (4 2 by 2 5 by up to 1 5 cm thick) described in the operation notes This showed no macroscopic abnormality beyond a number of small fresh hæmorrhages and distortion of the pattern by compression. On its deep surface was a smooth, slightly concave area (2 5 by 1 8 cm) representing a part of the tumour bed A vertical section through this to include both cortex and white matter showed on microscopic examination, plugging with thorotrast of a considerable number of capillaries and small veins in the white matter (Fig IV on Plate) With high magnifications unstained, brightly refractile particles were seen, as in Case I, at the periphery of many of the plugs, and occasionally in the cytoplasm of the adjacent endothelial cells Nowhere however, were particles seen outside the vessel walls In addition there were conspicuous areas of perivascular œdema and degeneration about many of the occluded vessels (Fig IV) Small foci of recent hæmorrhage were present in some of these areas Very few of the vessels in the grey matter contained plugs of thorotrast

COMMENT

During the 48 hours that elapsed between arteriography and the surgical removal of tissue the patient, in this case, was unconscious and showed an increase of hemiparesis This clinical disturbance appeared to be attributable to the injection of thorotrast; the histological examination of the vessels in the cerebral tissue forming the bed of the tumour supports this interpretation The appearances are similar to those in Case I but there are here, in addition, pronounced perivascular œdema and degeneration that appear to be due to the blockage of vessels by thorotrast. Such perivascular changes are not ordinarily seen in cerebral tissue adjacent to a meningioma. That they are present here but not in Case I is perhaps accounted for by the longer interval of time after arteriography The failure of the granules of thorium dioxide to gain the adventitial tissues can be explained by the absence of local inflammation in this case and the well known relative impermeability of the cerebral capillaries when inflammation is absent. From our experience in Case I it is probable that thorotrast was also retained in other areas adjacent to the tumour including the upper part of the motor cortex this would explain the unduly slow recovery from the hemiplegia after operation

Case III

Female aged 10 years. Chronic hæmolytic streptococcal abscess of temporal lobe Arteriography Enucleation of abscess.

CLINICAL HISTORY

She had complained of headache and vomiting for four months For two days at the beginning of the illness there had been pain and swelling of the neck—on which side was uncertain. Epileptiform convulsions had occurred but details were not available Examination revealed severe bilateral papillœdema, blindness of the left eye great contraction of the right visual field and a nasal hemianopia. There was slight left facial weakness and an increase of tone and of the tendon jerks in the left arm and leg The spinal fluid was under a pressure of 300 mm it contained 7 cells per c.mm and 80 mg of protein per 100 c cm. The skull was normal on radiographic examination and the eardrums appeared healthy

Arteriography was performed on March 11th, 1936 under avertin gas and oxygen 10 c.cm. of thorotrast being injected into each common carotid artery On the right side were seen the typical appearances of a temporal lobe tumour—namely marked elevation and compression of the Sylvian group of vessels and some forward displacement of the terminal portion of the carotid siphon A diagnosis of temporal lobe tumour was therefore made abscess being considered unlikely in view of the healthy tympanic membranes

A right lateral osteoplastic flap was turned immediately afterwards, and a chronic encapsulated abscess dissected out from the temporal lobe An interval of approximately 4½ hours elapsed before the abscess was completely removed A small thin portion of superficial cerebral cortex was removed with the abscess In the region of the tegmen tympani the dura was adherent to the abscess wall from which it appears that the abscess was secondary to otitis media. The patient made an uneventful and complete recovery except for severe impairment of vision

PATHOLOGICAL EXAMINATION (S.D. 717/1936)

The material received was a pyriform mass measuring 8 by 3·5 by 4·5 cm. It was composed of a central cavity containing thin turbid reddish brown fluid and flakes of fibrin and surrounded by a smooth shell, from 0·15 up to 0·7 cm. thick, of tough greyish brown tissue studded with miliary and slightly larger yellow inspissated abscesses The only recognisable cerebral tissue present was a small plaque of superficial temporal cortex, measuring 5 by 3 cm

A section through the temporal cortex and subjacent wall of the cavity showed the typical appearance of a chronic brain abscess There was no evidence of thorotrast in the blood vessels but a few granules were identified within perivascular phagocytes deep in the abscess wall.

COMMENT

The presence of thorium dioxide within adventitial phagocytes again demonstrates the greatly increased permeability of the cerebral capillaries in an inflamed area The material is in other respects unrewarding because so little of the adjacent brain was available for examination. The superficial fragment of temporal cortex was devoid of thorotrast but it is possible, in the light of the preceding cases that examination of the white matter adjacent to the deeper parts of the abscess would have yielded a positive result.

Case IV

Male aged 43 years. Secondary carcinoma of right cavernous sinus Arteriography five months before death.

CLINICAL HISTORY

He had noticed drooping of the right upper eyelid in March, 1935 and several months later he developed severe pain in the right eyeball. This pain, which was intense and constant subsequently involved the right side of the face and was his chief complaint In February 1936 he was admitted to the National Hospital, Queen square Examination revealed slight right ptosis and proptosis the right pupil was larger than the left although the reflexes of each were brisk; there was slight diminution of sensibility to pin prick in the area of skin supplied by the first division of the right trigeminal nerve Complete paralysis of the right external rectus muscle subsequently developed. Arteriography was performed on April 3rd, 1936 by Mr Harvey Jackson who has kindly allowed us to publish these details *In order to obtain views of the* cerebral blood vessels in two planes, two consecutive injections of 18 c cm. and 15 c.cm of thorotrast were made into the right internal carotid artery The radiograms did not reveal any aneurysm. During the injection he experienced sudden intense pain in the right eye Two hours later there had developed swelling and chemosis of the right upper and lower eyelids, with some impairment of vision and slight limitation of ocular movements in every direction During the next few days the lids were so swollen that the eyeball could not be examined A fortnight later all swelling had subsided and the eye movements were the same as before arteriography It was assumed that the injection had produced an aseptic cavernous sinus thrombosis.

When admitted to the London Hospital in August 1936 he was still experiencing great pain and examination revealed the following physical signs: the optic discs were flat and the visual fields normal there was considerable proptosis of the right eye which was immobile except for a slight degree of outward movement and its pupil was dilated and fixed; there was severe sensory impairment and complete motor paralysis in the distribution of the right trigeminal nerve; severe right facial weakness of the infranuclear type with loss of taste over the right side of the tongue Radiography of the skull was not helpful The cerebro-spinal fluid showed a slight increase of protein (0·0[illegible] g per 100 c cm.) The Wassermann reaction in both blood and cerebro spinal fluid was negative

The diagnosis was considered to be a tumour in the region of the cavernous sinus probably a meningioma-en plaque of irremovable nature In order to give relief from the intolerable pain it was decided to divide the right trigeminal nerve by the cerebellar route The operation took place on August 2[illegible]th 1936 but the patient died on the following day from reactionary hæmorrhage in the posterior fossa.

MACROSCOPIC EXAMINATION (P.M. 3[illegible] 1936)

The right middle fossa appeared normal superficially but on dissection the right cavernous sinus and adjacent Gasserian ganglion were replaced by [illegible] greyish white tissue forming a mass 1·3 by 1·3 by 1 cm, lep

This protruded anteriorly through the superior orbital fissure and infiltrated the posterior 1 cm of the soft tissues of the orbit The sheath of the internal carotid artery in the petrous portion of its course was thickened and infiltrated, but neither the adjacent bone nor the pituitary fossa were macroscopically involved No tumour was found in the rest of the body, but the skull was not split to expose the nose, accessory sinuses, and nasopharynx

MICROSCOPIC EXAMINATION

Coronal sections through the hinder part of the orbital contents and through the Gasserian ganglion and cavernous sinus show great fibrosis and a diffuse infiltration of the tissues with polygonal celled secondary carcinoma Refractile, unstained granules of thorium dioxide are present in macrophages, usually about the adventitia of veins and arterioles (Fig V on Plate) of the orbital tissues and of the tumour Similar granules are often present in small numbers in the media of arterioles in the following situations the septa of the hinder parts of the ocular muscles, right lateral border of the optic chiasm and nerve and adjacent meninges, the posterior lobe and pars intermedia of the pituitary gland and in one arteriole only in the anterior lobe Arterioles so affected frequently showed an endarteritis fibrosa, in the single arteriole affected in the anterior lobe of the pituitary there is endothelial proliferation No changes were observed in the nervous tissue of the optic tract adjacent to affected arterioles Phagocytes containing thorium dioxide are present in the fibrous tissue stroma of the tumour Particles are also present in cells, similar to those that ordinarily store pigment, in the posterior lobe of the pituitary

No thorium dioxide was identified in sections through the right gyrus rectus and the lower part of the right Rolandic region with their leptomeninges

COMMENT

The complete paralysis of trochlear and oculomotor nerves which eventually developed in this case was doubtless due to the compression of these nerves, together with the less completely affected abducens, by carcinoma in the superior orbital fissure The striking clinical disturbance that followed in two hours the injection of thorotrast and persisted for two weeks can only be explained by obstruction of ophthalmic veins or, possibly, capillaries It was regarded at the time as due to aseptic thrombosis of the cavernous sinus When the cavernous sinus was examined microscopically five months later it was found to be obliterated by cancerous infiltration No iron pigment was present, so that it is very unlikely that the obliteration was preceded by thrombosis We consider it more probable that the disturbance was due to plugging of vessels with thorotrast, as demonstrated in Cases I and II The gradual subsidence of symptoms presumably accompanied the dispersal of the plugs of thorotrast The presence of granules of thorium dioxide in macrophages round venules suggests that this substance was dispersed by passage through the walls of the occluded vessels It cannot, however, be taken as definite evidence of this method of dispersal, because similar macrophages surrounded arterioles, and we have not yet found arterioles occluded with thorotrast, moreover, occlusion of arterioles would not have caused the clinical signs The association of these deposits with an endarteritis fibrosa recalls the observation of Fleming and Chase (1936) of a portal fibrosis of the liver in a human subject five months after an intravenous injection of thorotrast There is also, however, a possibility that the endarteritis fibrosa preceded arteriography and facilitated the retention of the thorotrast

The site of the primary tumour in this case is unknown At necropsy the possibility of metastasis, although considered, was regarded as unlikely in view of the long history and the absence both of a primary tumour and of secondary deposits elsewhere in the body The possibility of a primary carcinoma of the nose, accessory nasal cavities, or nasopharynx cannot be ruled out as the skull was not divided sagittally at necropsy, but a clinical examination made specifically for this purpose did not reveal any tumour in this region

Five Other Cases

Histological investigation of the following fi cases in which arteriography had been performe failed to reveal any retention of thorotrast withi the brain

Case V—Female, 41 years Right frontal spongioblastoma multiforme One day before death 11 c cm of thorotrast were injected into each common carotid artery with good results After needling of both frontal lobes and identification of tumour tissue the patient did not recover consciousness

Case VI—Male, 37 years Right fronto temporal spongioblastoma multiforme Four days before death injections of 15 c cm Hippuran and 15 c cm thorotrast into the right common carotid artery failed to give satisfactory radiograms The left cerebral vessels were well seen after injecting 15 c cm of thorotrast into the left common carotid artery Three days before death bifrontal ventricular estimation was carried out afte which the patient did not recover consciousness

Case VII—Female, 50 years Left frontal meningioma Eight months before death 16 c cm thorotrast were injected into each common carotid artery, and the cerebral vessels were successfully demonstrated The tumour was partially removed in several stages

Case VIII.—Male, 66 years Suprasellar meningioma Arteriography was carried out 2 days before death, a good result being obtained on the left side and a moderate on the right The tumour was partially removed on the next day Death was due to excessive hæmorrhage at operation.

Case IX—Male, 41 years Secondary carcinoma of right parietal lobe Primary carcinoma of stomach Arteriography was successfully performed on the day before death

Discussion

Retention of thorotrast in the intracranial circulation and its passage through the endothelium to be stored in macrophages have been described in four cases † In Cases II and IV arteriography was associated with clinical disturbances which were assumed at the time to be of a vascular nature. In Case IV these disturbances resolved spontaneously and almost completely, histological examination showed that all the thorium dioxide was outside the vessels or in their walls In Case II however the disturbance was of much longer duration, the severe hemiplegia and aphasia which persisted after operation, and from which the patient has as yet only incompletely recovered, were out of all proportion to the severity of the operative manipulations and indeed began immediately after the injection of thorotrast. It appears certain that some of this delay in recovery has been due to the vascular occlusion described. In Case I death took place 21 hours after the injection and during this period the patient did not regain consciousness There can be little doubt that arteriography precipitated his collapse and death. In Case III there was no clinical disturbance referable to the injection of thorotrast; histological evidence of retention in this case is extremely *meagre*.

---

† While this paper was in the press a fifth case was found in a woman aged 46 years Arteriography was performed when she was in extremis and death followed a few hours later At necropsy (P M 519/1933) a large ill defined homogeneous mass (5 by 4 7 by 4·2 cm) of pinkish grey granular tissue was found in the right basal ganglia and hypothalamus It had caused considerable distension of the left lateral ventricle especially of the occipital horn where the ependyma of the outer wall was elevated over a pocket of cerebro spinal fluid to form a cyst (3 cm in diameter) Microscopic examination of a section of the occipital lobe including the ependymal margin of this cyst shows conspicuous distension and occlusion with thorotrast of many capillaries and veins in both the cortex and white matter A few veins in the leptomeninges are similarly affected There are no changes in the perivascular nervous tissue The tumour like mass is histologically a granuloma which does not conform to any recognised type A few capillaries in it are also occluded with thorotrast Two additional features are therefore presented by this case (1) retention of thorotrast in cerebral tissue remote from the dominant pathological lesion perhaps determined in this instance by focal internal hydrocephalus and pressure from the adjacent cyst (2) the presence of thorotrast in veins of the leptomeninges

The lesions in these four cases were of a widely different character: an old cerebral hæmorrhage of considerable size a meningioma of the falx a chronic abscess of the temporal lobe, and lastly a secondary carcinoma of the cavernous sinus It is clear therefore that retention of thorotrast is not associated with any one pathological condition Although so divergent in this respect they possess one feature in common that in each there was considerable local compression of the tissues which may have caused some obstruction to the flow of blood In Case IV it is possible that a pre existing endarteritis fibrosa was responsible for or contributed to the retention Cases V to IX show that retention of thorotrast does not constantly occur in the neighbourhood of intracranial tumours Our failure to demonstrate it in two examples of spongioblastoma multiforme (Cases V and VI) may perhaps be due to the ill defined and infiltrating character of these tumours Cases VII and VIII on the other hand show that retention of thorotrast need not necessarily occur in the neighbourhood of a compressing tumour Further investigation is needed to elucidate the factors that may lead to retention in one case but not in another of similar pathological character

A second question concerns the subsequent fate of lesions in a non inflammatory area such as were described in Case II Will the blocked vessels in such areas regain their patency and will the perivascular areas of œdema and degeneration be restored to normal or will these areas be ultimately replaced by scar tissue?

Clearly thorotrast can no longer be regarded as an innocuous substance While we do not question its value in cerebral arteriography as a means of localisation and the fact that it can be used in a number of cases without immediate harm the possibility of two grave sequelæ needs consideration first disorders due to blockage of vessels which may lead to a permanent disability sufficient to spoil the results of operation and secondly the possible production of tumours in later years through the known radio active properties of thorium dioxide It may be argued that the amounts retained in the tissues are too small to produce this remote effect yet the production of sarcoma in the rat in approximately twelve months after the subcutaneous injection of as little as 0 6 c cm of thorotrast (Selbie 1936) suggests that this danger must not be ignored It is therefore important that an innocuous substitute for thorotrast should be found Until then we suggest that thorotrast should be used only for cases in which the exact diagnosis cannot be effected by other means

Summary

Four cases have been described in which histological evidence was obtained of retention after arteriography of thorotrast in the lumen or walls of cerebral vessels or in perivascular macrophages

Such retention appears to be liable to take place in the neighbourhood of compressing lesions such as meningioma, a large hæmorrhage, or chronic abscess

The aggravation of clinical symptoms that was observed in two of the cases, and retardation of recovery *from operation in one* may be attributable to this occlusion of vessels by thorotrast

The use of thorotrast is inadvisable unless exact diagnosis is unattainable without it

POSTURAL DRAINAGE

By H V Morlock M C M D M R C.P Lond

PHYSICIAN TO THE CHEST HOSPITAL, VICTORIA PARK, LONDON
THE MILLER GENERAL HOSPITAL, GREENWICH AND
THE HAMPSTEAD GENERAL HOSPITAL

(WITH ILLUSTRATIONS ON PLATE)

Postural drainage has long been used as a therapeutic measure in the treatment of bronchiectasis and lung abscess For many years however this drainage was very intermittent and dilatory the patients being advised to please themselves in the position of drainage for a short period on rising and again before retiring at night. This form of treatment was not valued very highly so that the advice about it was not particularly emphasised and therefore the patients were prone to neglect completely a procedure that was somewhat inconvenient to themselves. More recently the value of this method has been more fully appreciated and attempts have been made to make this method less intermittent, more prolonged and more valuable To this end the late Mr H P Nelson introduced his postural drainage bed and my late colleague Dr A J Scott Pinchin and myself suggested an inexpensive modification which the patients could take home with them and so enable them to make the treatment a matter of daily routine for years if necessary

THE METHOD

When patients suffering from pulmonary suppuration are admitted into hospital they are nursed in these postural drainage beds. At first they are placed in a position of drainage for a few minutes at a time but the period of drainage is rapidly increased and soon the patients will tolerate the position for one to two hours at a stretch eventually sleeping through the night, as well as spending a large part of the day in the position of drainage. When they leave hospital they are provided with a bed for use at home and so even during their hours of rest, they are definitely undergoing a valuable therapeutic measure For example a patient with bronchiectasis at the left base is advised to sleep on the right side with body flexed sideways at the hip the hip lying just below the apex of the drainage bed In this position the trachea would be inclined well downwards and would lie well below the level of the bronchiectatic area If the patient is not using a drainage bed he can obtain a satisfactory position by sleeping on the right side and raising the foot of his bed not less than 20 in. When this method is properly carried out there is no doubt that it is an extremely valuable therapeutic procedure, and I personally have used it in 43 cases of abscess and 69 cases of bronchiectasis with gratifying results If a faulty position of drainage is used during sleep, however, infected sputum may drain from the diseased lung into the main bronchus of the sound lung and become aspirated into the alveolæ, producing an acute pulmonary abscess in the area into which it has become aspirated. The following cases are examples of this —

CASE 1 —A man, aged 38, suffered from left basal bronchiectasis of some years' duration (Fig I on Plate) Admitted to hospital and instructed in postural drainage, in which position he slept and spent most of the days, "coming up" only for feeding and toilet On this régime and repeated bronchoscopic washouts he improved very considerably, the sputum becoming odourless and reduced in quantity On leaving hospital he returned to work and continued postural drainage at nights, lying on the right side, but he became careless about raising the foot of the bed After seven months he became acutely ill with increase in quantity and odour of his sputum Physical and radiological examination (Fig II on Plate) show a large lung abscess at the right upper lobe This was treated by bronchoscopic lavage, and cleared up in four treatments (Fig III on Plate) Recently he agreed to undergo the operation of lobectomy but owing to adhesions it was found impossible to remove the lobe complete He died 7 days later Post mortem there was extensive left lower lobe bronchiectasis but no evidence of the abscess in the right upper lobe

CASE 2 —A boy, aged 16, known to have had an atelectatic bronchiectasis for 8 years Admitted to hospital, he underwent the same régime as Case 1 and did very well On leaving hospital he continued nocturnal postural drainage by sleeping on the right side but without troubling to raise the foot of the bed sufficiently He was readmitted 5 months after leaving hospital with fever and an increase in the sputum Radiological examination showed an area of pneumonitis at the right upper lobe On treatment in the orthopnœic position with simple expectorant mixtures the pneumonitis cleared up

CASE 3 —A man aged 50, suffered from right lower lobe bronchiectasis He was instructed in postural drainage and carried it out at home during the hours of sleep, but was content to lie on the left side without raising the foot of the bed sufficiently Improved in health considerably for 5 months and then developed fever and an increase in sputum Returned to hospital, where physical and radiological examination showed an abscess cavity in the left upper lobe Patient refused to be readmitted The recent lung abscess is progressing favourably however on weekly bronchoscopic washouts, expectorant mixtures, and sleep in the orthopnœic position

COMPLICATIONS AND THEIR CAUSE

From a study of the notes of over 200 cases of bronchiectasis which I have personally treated in hospital, I have only found one case that developed a lung abscess in the sound lung, and that was in a child with bronchiectasis who had had an oleothorax performed on the affected side, and yet this complication occurred in three out of 69 cases undergoing postural drainage at home

I have never seen the complication while the patient was undergoing postural drainage under observation in hospital, although they were spending a considerably longer part of the day in the position of drainage than they did at home, when the period was confined to the hours of sleep and when the position assumed was not controlled This suggests that it is the faulty position during the night, when the cough reflex is diminished by sleep that is responsible for the development of the aspiration abscess All these patients admitted that they had failed to tip the thorax downwards and had been content to lie on the sound lung Fig IV will demonstrate the dangers of this faulty position.

In considering the ætiology of pulmondry suppura tion after operation under a general anæsthetic, there has always been two views one, that the pulmonary suppuration was the result of an emboli phenomena from the site of the operation, the other, that it was the result of direct aspiration of infected material from the upper respiratory tract during anæsthesia and the semi comatosed period following it

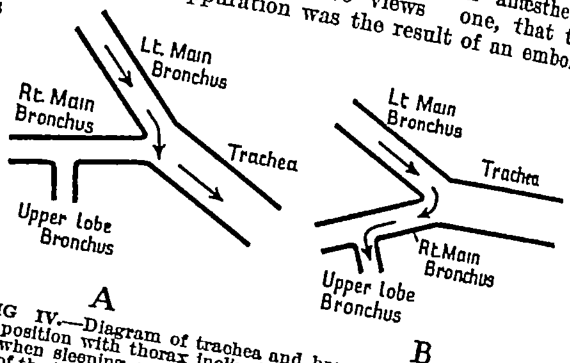

FIG IV.—Diagram of trachea and bronchi showing (A) corre position with thorax inclined well down (B) faulty positio when sleeping on the side without the downward inclinatio of the thorax.

It has already been demonstrated that lipiodol introduced into the upper respiratory tract during sleep will pass the glottis and will be found in the lungs when a skiagram is taken. The cases described here show that infected sputum allowed to collect in a dependant bronchus will produce a lung abscess These last two facts, in my opinion, lend consider able confirmation to the aspiration theory of pos anæsthetic pulmonary suppuration A further perus of Fig IVB, and the fact that the secondary absc developed in the upper lobe of the lowermost lung, show that during sleep the sputum within the bronchi obeys the law of gravity, and thus confirm the value of properly carried out postural drainage during sleep

CONCLUSIONS

From these cases it is concluded that the correct position for nocturnal postural drainage is one in which the right and left main bronchi are on the same horizontal plane, and in which the trachea is lower than the bronchiectatic area In other words, the patient should sleep on the abdomen with the ang between the groins and the abdomen on the ap of the postural drainage bed, or lie on the abdome with the foot of the bed raised at least 20 inches.

THROMBOSIS OF THE POPLITEAL AND FEMORAL ARTERIES

BY A M BOYD, M.B Lond., F R C S Eng
FIRST ASSISTANT TO THE SURGICAL PROFESSORIAL UNIT, ST BARTHOLOMEW'S HOSPITAL, LONDON

(WITH ILLUSTRATIONS ON PLATE)

RECENT investigations suggest that thrombosis of the popliteal and femoral vessels is by no means an uncommon condition Sir Thomas Lewis has pointed out the extreme difficulty in distinguishing primary thrombosis from embolism, because a thrombus forms upon an embolus Serial section of the clot is seldom of any assistance in determining the sequence of events This paper is based upon seven cases of thrombosis of the popliteal and femoral vessels investigated in the wards of the surgical unit at St Bartholomew's Hospital.

ÆTIOLOGY

Primary thrombosis is undoubtedly more frequent than is generally supposed. The thrombosis is always preceded by disease of the vessel wall, which gradually narrows the lumen until finally clotting occurs There is thus time for the collateral circulation to develop a fact which accounts for the paucity of symptoms The popliteal artery is more commonly affected than the femoral. Sometimes both vessels are affected when the popliteal thrombosis is always the primary event

PATHOLOGY

The most common pathological change is an atheromatous degeneration of the vessel wall Thrombo angiitis obliterans is less often the cause and its incidence in the present short series gives an erroneous impression of its importance Thrombo angiitis in younger people is more often investigated thoroughly whereas older people with atheroma are less likely to come to the surgeon except for amputation In the popliteal artery the earliest changes are observed in the segment of the vessel which lies at the level of the condyles of the femur The lumen is narrowed until finally thrombosis takes place and the clot extends up to the origin of the anastomotica magna artery The reason for the localisation at these sites is probably concerned with strain The part of the popliteal artery where these changes are observed is the segment least supported and is constantly being strained by the movements of the knee The localised patches of atheroma in the femoral artery are less easily explained

SYMPTOMS AND SIGNS

The only symptom in an uncomplicated case is intermittent claudication usually mild but sufficiently severe to handicap the patient. The cramping pain in the calf on exercise is due to an insufficient supply of blood to the muscles since the collateral circulation is unable to provide the increased volume of blood demanded by the muscular effort In only 2 out of the 7 cases were there any symptoms at the site of thrombosis These two patients noticed a slight tingling sensation over the affected segment of the artery If in addition to blockage of the main vessels there is obliterative disease of the tibial or plantar arteries there will be rest pain usually in the foot and if the disease process extends to the arterioles there will be indolent ulceration and gangrene

On examination of an uncomplicated main vessel obstruction the leg and foot appear normal in colour while in the horizontal position There will, however be well marked postural colour changes the limb paling rapidly on elevation and becoming suffused on lowering it below the level of the heart The surface temperature taken at several points down the limb shows a normal temperature gradient falling steadily towards the periphery Pulsation is well marked in the femoral artery in Scarpa's triangle and is usually absent in the posterior tibial and dorsalis pedis arteries because of spasm or failure of transmission of the pulse wave owing to the arterial block Pulses should never be pronounced absent without examining the limb after warming either by a heated cradle or immersion in a bath at 45 C

Oscillometry is very valuable in finding approximately the site of an arterial block and Boulitte's modification of the Pachon oscillometer has been used in these investigations It is however no more than a rough bedside method and gives only approximate information Oscillations may be absent below a grossly diseased but still permeable segment of a vessel or if the walls are calcified

ARTERIOGRAPHY

Direct visualisation of the vessels is essential when a block is suspected in order to define its exact extent and to assess the condition of the collateral circulation

The patient is given morphine gr 1/6 and hyoscine gr 1/150 three-quarters of an hour before operation He is placed on the X ray table with the limb lying slightly flexed at the knee and with the outer side flat upon the table This position can be comfortably maintained by placing a sandbag under the opposite buttock Two intensifying screens are used and a film 15 by 12 in is placed under the limb including the lower third of the thigh and the upper two thirds of the leg The X ray tube is centred over the middle of the popliteal space The subcutaneous tissues and the sheath of the common femoral artery are infiltrated with 0·5 per cent novocain and the vessel exposed through an incision 1½ in long. A 20 c cm. record syringe is filled with Thorotrast and is mounted with a Moniz needle which is 0·8 mm internal diameter (B W G 18) and set in a mounting bent in two right-angles to allow it to be introduced obliquely through the arterial wall thus making a valvular opening and minimising the risk of hæmorrhage Then 16 c.cm. of thorotrast is injected as fast as possible and the exposure made as the last few c.cm. are being injected

Arteriograms are reproduced to illustrate the typical appearances of a blocked vessel and the characteristic tortuous hypertrophied collateral vessels (see Figures on Plate)

TREATMENT

Obliterative vascular disease has hitherto been considered outside the range of surgery and its treatment is still in the experimental stage Leriche first suggested excision of the obliterated segment on the grounds that the thrombosis caused irritation of the nerves in the vessel wall and produced spasm of the distal vessels

Arterectomy is followed by a dilatation of the collateral vessels and increased warmth of the limb It has been claimed moreover that it relieves pain

Intermittent claudication—CASE 1 A man aged 72 Referred for examination by Dr Worster Drought and complaining of intermittent claudication in both legs. Arteriography showed thrombosis of a segment of both superficial femoral arteries (Fig I on Plate) The collateral circulation and the condition of the distal vessels were good Segments of both thrombosed vessels were excised by Mr G C Knight with complete relief of pain. Sufficient time has not yet elapsed to say whether relief is permanent

Rest pain—In this condition there is disease of the distal vessels and therefore permanent relief cannot be expected. Temporary relief may be obtained by arterectomy

CASE 5—A chauffeur aged 49 Complaining of intermittent claudication in the calf of about one year's duration Six weeks before admission rest pain began in foot which became agonising and required morphia gr ¼ t.d.s in order to obtain any relief Arterectomy of a segment of left popliteal vessel was performed with complete relief of the pain. Unfortunately pain recurred three months later and eventually amputation was performed elsewhere

OTHER ILLUSTRATIVE CASES

CASE 2—A man aged 60 While rising from a chair he felt a cramping pain in his right calf Next morning he noticed his second and third toes were pale and cold but not painful This disappeared after a few days

Walking induced in the right calf typical intermittent claudication, which gradually increased Examination showed well marked postural colour changes Femoral, post-tibial, and dorsalis pedis arteries palpable, popliteal pulse absent Blood pressure 176/86 mm Hg Wassermann reaction negative (Fig II)

CASE 3 —A man aged 47 Gradual onset of intermittent claudication in right calf eighteen months ago Pains came on walking for decreasing distances, and the right big toe became discoloured and sore Examination showed postural colour changes in the right leg, the big toe was somewhat cyanosed and there was slight soreness of inner nail fold No pulsation felt in any vessel below the femoral Blood pressure 130/90 mm Hg Wassermann reaction negative (Fig III)

CASE 4 —A man aged 56 Gradual onset of intermittent claudication in right calf Some precordial pain on exertion Examination showed postural colour changes in both legs, absent popliteal and dorsalis pedis pulses Blood pressure 112/100 mm Hg Wassermann reaction negative (Fig IV)

CASE 6 —A man aged 36 Eighteen months before admission he began to suffer from pain in right instep and under heads of metatarsal bones, "as if arch was dropping," coming on after walking 500 yards Diagnosed and treated as an orthopædic condition Little toe became sore and eventually gangrenous, followed a few months later by the third toe On admission he had severe rest pains in his big toe, which was discoloured, the second and third toes were gangrenous No pulses were felt below the femoral artery in either leg Arterectomy of popliteal artery produced no relief and amputation had to be carried out (Fig V)

CASE 7 —A man aged 32 He complained of intermittent claudication in both calves for 14 years Recently pains had been worse, coming on after walking 20 yards, During the last three months he had constant burning pain in the right big toe and instep Examination showed postural colour changes in both legs no pulses could be felt in either lower limb below the femoral (Fig VI)

Analysis of Cases

Case	Age	Disease	Arteries blocked			Symptoms		
			Femoral	Popliteal	Distal vessels	Intermit claud	Rest pain	Gangrene
1	72	Atheroma	+	−	−	+	−	−
2	60	"	+	+	−	+	−	−
3	47	"	−	+	−	+	−	−
4	56	"	+	−	−	+	−	−
5	49	Thrombo angiitis obliterans	−	+	+	+	+	−
6	36	"	−	+	+	+	+	+
7	32	"	−	+	+	+	+	−

SUMMARY

Seven cases of main vessel obstruction are reported and analysed (see Table) While it is too early yet to speak authoritatively on the results of arterectomy the operation appears to offer the patient relief of his symptoms and time will show whether the benefit is sufficiently prolonged to justify the operation The likelihood of relief of symptoms and the ultimate prognosis varies with the level of the block. The more distally the block is situated, the graver the outlook

---

CLINICAL AND LABORATORY NOTES

HERNIA STRANGULATED INSIDE A PROLAPSED AND INVERTED COLON

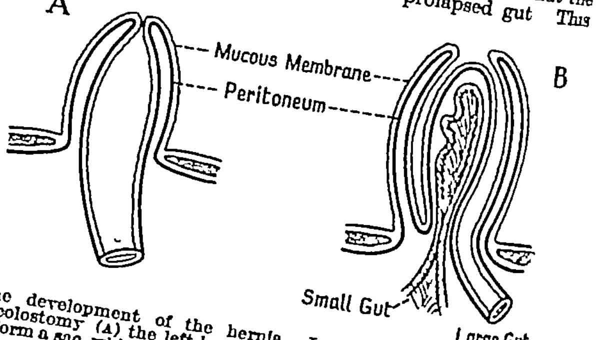
BY P G HARVEY, M.D, B S Lond.
HON SURGEON TO THE MONMOUTH HOSPITAL

A MAN aged 35, a postman, was admitted to the Monmouth Hospital suffering from a prolapse from a left inguinal colostomy For some years he had had a colostomy, and there had been a protrusion, about the size of a clenched fist, which was easily reduced and which caused no inconvenience as long as he wore a colostomy belt Whilst mounting his bicycle about 11 A.M he had had the feeling of something "giving away," had experienced considerable pain, and had found the protrusion greatly increased in size He had had nausea but had not been sick. The pain had got worse and he was seen by his doctor about 5 P M and admitted to hospital at 7 30

The patient's former history, obtained from the Ministry of Pensions, Newport, showed that when he was admitted to hospital after being wounded there was a large cavity in the sacral region The bladder and the lower end of the torn rectum seemed to lie at the bottom of the wound, the whole sphincter and lower 3 in. of the rectum having been carried away A left inguinal colostomy was performed. A large portion of bowel remained constantly prolapsed and could not be replaced In 1922 he was fitted with a colostomy plug and retaining belt which retained the artificial anus in position quite satisfactorily

On admission the patient showed severe shock From the left inguinal colostomy a large protrusion extended right across the abdomen It was about 15 in long and 6 in in circumference and very tense but the mucous membrane was not unduly congested. At the distal end there was a narrow slit, obviously the original opening into the gut from which a small quantity of fluid fæces was escaping The whole protrusion resembled a greatly exaggerated prolapsus ani A further examination under ether showed that the mucous membrane was attached to the skin all round the colostomy opening and that there was no sulcus I can best compare the condition present to a finger of a glove fixed to the colostomy opening

All attempts at reduction failed, and I decided that the best thing to do was to resect the prolapsed gut This



The development of the hernia In the original prolapsed colostomy (A) the left hand wall prolapses into the lumen to form a sac which contains small intestine

I was about to do when it struck me that it would be wise to open the very tense protrusion first I did so, and found that it consisted of the whole thickness of the gut, which was inverted so that the inner surface of the protrusion consisted of the peritoneal surface of the descending colon (see Figure) Inside the sac so formed I found 3 or 4 ft of intensely congested small intestine and a large piece of omentum These were reduced with great difficulty I then clamped and cut away the prolapsed gut, tied in a Paul's tube, and stitched the mucous membrane to the original colostomy opening The patient's condition on leaving the table was very bad.

On Dec 26th there was a slight discharge of fluid fæces from the tube and the general condition was still bad, but there was no sickness. He was given 0·5 c cm pituitary extract every four hours Next day his general condition was rather better but there was very little discharge from the tube On Dec. 28th he complained of nausea and distension of the abdomen There was no discharge from the tube his general condition was very bad, and there was slight delirium After the dressing he put his hand under the bandage and pulled the Paul's tube away I decided not to replace the tube but coaxed a 1 inch rubber tube into the opening of the bowel This was followed by the discharge of some pints of foul-smelling fluid fæces The tube was fixed to the bandage Next day the general condition was much better; the tube was draining freely and there was no *distension. The drain was removed on Dec 31st when* fæces were coming freely from the colostomy opening He was discharged from hospital on Jan 8th, and now seven years later remains perfectly well

This is a condition I have never heard of nor can I find a record of a similar case in any book on surgery that I have consulted

"FIXATION ABSCESS OF BONE DUE TO BRUCELLA

By J L Edwards M.B Camb M.R.C.P Lond
ASSISTANT PATHOLOGIST ST THOMAS'S HOSPITAL, LONDON

For fifteen years, following a car accident a healthy athletic man moved about comfortably with a plated femur Two weeks of increasing disability and pain in the neighbourhood of the plate preceded admission At operation a mixture of pus and blood was found around the plate which was removed Brucella was isolated from this fluid Blood culture was sterile No history suggestive of undulant fever at home or abroad, was elicited The patient stated he had taken for years at breakfast each morning cereal food with unpasteurised milk from a local farm

He was a man aged 41 a clerk living in Hertfordshire He was admitted to St Thomas's Hospital on Nov 2nd 1936 complaining of pain in right thigh brought on by walking and was discharged on Dec 30th He had served in Gallipoli in 1915 and had had dysentery but gave no history of undulant fever at home or abroad His right femur was fractured in a car accident in 1921 and was plated Recovery was uneventful though the knee remained rather stiff A fortnight before admission the right leg hurt on walking and a few days later there was a swelling above the knee After a week the temperature was 10_ 5 F

State on admission—Healthy and athletic appearance Temperature 99·8 F Pulse rate 88 Left leg normal Right leg: no wasting scar extending over mid third of lateral side of right thigh tender over mid third on palpation limitation of movement of knee flexion to 130 Urine: nil abnormal Pathological report: leucocytes 6000 (polymorphs 46 per cent small lymphocytes 41 per cent large hyalines 12 per cent mast cells 1 per cent) Radiography: no evidence of active infection plate present

Operation—A cavity over the plate contained 2 oz. of pus There was some necrosis around the plate some screws came out easily others not The plate was removed and the bone scraped to remove débris a drain was left in

Subsequent progress—The temperature which was 101 F on the day after operation, fell to normal. There was a discharge of bloody fluid from the drain followed by pus for two weeks The drain was taken out in four days On section tissue from wound showed pus blood and foreign débris. The pus removed at operation (mainly blood) gave a pure culture of brucella A blood culture ten days after operation was negative The spleen was not palpable the lymph glands were not enlarged and the patient was discharged fit four weeks after operation

The *serological findings* were as follows —

—	Titre.	Agglutination.
Serum of patient on Oxford type organisms	1/500	Caprine incomplete Bovine: complete. Porcine faint trace
Serum of patient on laboratory organisms	1/500	Bovine: marked Caprine marked
Serum of patient on organism of patient	1/1000	Complete
Organism of patient on laboratory serum	1/1000	Complete

The *culture media* used were Dorset's egg and blood agar Later the organism grew on agar alone (in normal atmosphere) The growth was obvious in four days Culture in sugars showed progressive alkalinity

It seems that in this patient brucella, circulating in the blood without giving rise to recognisable symptoms produced a fixation abscess about the plate on the fifteen years old fracture The patient's serum strongly agglutinates his own and standard brucella, but blood culture was negative The variety is probably *Brucella abortus*

I wish to thank Mr B W Williams for permission and encouragement to publish this case

PHENOBARBITONE—A CAUTIONARY NOTE

By J Tylor Fox, M D Camb D P M
MEDICAL SUPERINTENDENT LINGFIELD EPILEPTIC COLONY SURREY

Phenobarbitone—more familiar under such names as Luminal and Gardenal—has very largely replaced bromides in the routine treatment of epilepsy Where it is effective it usually acts promptly and the attacks cease within a day or two sometimes never to recur More often tolerance sets in within a few weeks and then an increased dose may again abolish the fits Renewed recurrence after a further period of freedom may tempt the doctor to increase the dose still further with the result that many patients are taking 4 or 5 grains a day or even more

Experience has taught me that such patients are living dangerously The omission or reduction of their medicine is liable to be followed within a very few days, by a grave increase of fits or even by status epilepticus

Some hundreds of patients have been admitted to the Lingfield Colony who were taking phenobarbitone at the time of admission. The amount which they were taking has shown astonishing variation One tenth of a grain is the smallest daily dose of which I have a record but at the other end of the scale I have met with 6 grains a day on three or four occasions The practice of starting with a small dose and working upwards is obviously a sound one but I suggest 3 grains a day as a maximum The practitioner who goes beyond this should recognise that unless his patient is prepared to continue the dose indefinitely, there may be considerable risk when the time comes to reduce or withdraw the drug In any case, I suspect that large doses taken for long periods may be detrimental to the patient's mind, and, if they became general, would bring phenobarbitone into the same sort of discredit that bromide got into a generation ago

Increase of fits due to phenobarbitone deprivation or reduction is also liable to occur in patients whose fit-incidence has not been affected by the drug Thus a trial period may leave the patient definitely worse off than before

Further may I suggest the necessity of close observation of all patients, especially children, who are given phenobarbitone ? If 1 or 2 grains a day make them sleepy or dull, no notice need be taken, for the sleepiness will almost certainly pass off in a few days More often the patients will be brighter, the normal in intelligence and behaviour, this may be due to reduction or arrest of fits in some cases. But quite a number of children, as many as 20 cent in my experience, become more irritable and difficult when they are taking phenobarbitone. The condition may be a temporary one, and pass in a few days or weeks, or it may persist and grow, occasionally giving rise to something approaching mania This drug irritability is a very definite condition, and must be watched for It is not due to cessation of fits, because it is seen also in children whose fit-incidence is unaffected. Experience leads me to believe that there are many epileptic children whose grave conduct difficulties are directly caused or much increased by the phenobarbitone they are taking every day

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

At a meeting of this section held on Feb 3rd, the president, Prof G Grey Turner being in the chair, a discussion on

Injuries of the Peripheral Nerves

was introduced by Mr Harry Platt (Manchester) who freely illustrated his subject on the screen. A new generation of surgeons, he remarked, was coming into the field who had not had the opportunity of the great experience which the war afforded In the month of February, 1920, for example, he had himself explored 41 injured nerve trunks, whereas in civil practice in all the years since he had encountered only 89 cases of the kind. In that number the nerves involved were ulnar 55, median 15, brachial plexus 9, external popliteal 5, musculo-spiral 4, anterior tibial 1 In 39 the injury to the nerve was a complication of fracture or dislocation, in 32 of a penetrating wound. Many cases of nerve injury in civil life did not come to the operating theatre These lesions owned a variety of causes, and the clinical problem was protean In simple fractures peripheral nerve complications were uncommon In some cases the nerve involvement was only evident in the early weeks following injury

In dislocations and fracture dislocations of the shoulder joint, except for circumflex palsy, it was rare to find nerve complications In circumflex lesions, relaxation and re education resulted as a rule in recovery in three to four months In primary lesions of the infraclavicular plexus the prognosis was not unfavourable In true secondary lesions associated with an unreduced dislocation recovery was often delayed on account of the strangling effects exerted by the extensive scar tissue which formed round the dislocated head. The nerve trunks should then be freed without delay, either by open reduction or by excision of the head. Musculo-spiral palsy might be primary or secondary The former was usually the result of direct impact of a bony fragment, it might follow over zealous effort to manipulate the fractured portions into exact alignment Secondary lesions were due to the nerve trunk adhering to a projecting fragment or irregular bony surface, and the nerve trunk might be gradually obliterated by dense cicatricial tissue. As the musculo-spiral lesion accompanying simple fractures often recovered spontaneously, conservative measures should be tried. Nerve complications rarely followed fractures of elbow, nerve lesions did occur in fractures of the lower end of the humerus or in subluxation of the elbow joint. In 22 cases of epicondylar fracture ulnar nerve showed primary damage in all. Secondary lesions became evident three to four weeks after the date of the injury, and they were met with in both internal epicondylar and supracondylar fracture Owing to its more protected position, the median nerve was seldom implicated in elbow joint fractures, occasionally the nerve trunk was impaled on the projecting lower end of the shaft in a supracondylar fracture with gross backward displacement of the lower fragment. Nerve injuries from penetrating wounds were rarely met with above the level of the lower third of the forearm. When infection had already become established, failure of regeneration after primary suture was almost certain, any attempt at nerve repair should be put off until the condition of the wound had improved. Traction lesions of the brachial plexus were of two kinds those seen in the infant following difficult birth, and the adult cases, usually the sequelæ of road accidents. In the infant spontaneous recovery, partial or complete, usually occurred in the first few months. The plexus injuries in the adult were much more severe

Sir Robert Stanton Woods spoke of the help given by electrical testing in determining the best form of treatment. In every such injury a full and accurate history was most important The musculo-spiral, he had found, was one of the most recuperative nerves in the body Examination was of no assistance in the days immediately following the presumed injury, for electrical reactions gave indications solely of interference with the functions of excitability and conductivity The only positive proof of the hysterical nature of a paralysis was the muscle response to electrical stimulation, and in a paralysed limb the organic and the functional could be accurately segregated. Electrical testing would differentiate between muscles which failed to function because of pain and those which were affected by a lower motor lesion. He agreed with Lewis Jones that any deviation from the completely developed reaction of degeneration was important, sluggish response to stimulus by the direct current was diagnostic of a lower motor lesion, even in the presence of faradic excitability

Mr F H. Bentley described some experiments he had been carrying out at the Royal College of Surgeons on the surgery of nerve-roots. It was found that when a nerve was sutured union took place by scar formation the scar filling the interstices and so obstructing the newly growing nerve fibres Direction was given to the nerve fibres by the scar tissue rather than by a new organised pathway When accurate approximation of the nerve ends was not secured, there was a relative increase in the amount of scar tissue formation Silk excited much less tissue reaction than did any other suture material.

Prof J **PATERSON ROSS** said that in 5 cases of median nerve injury and 12 of ulnar nerve damage the effects following secondary suture were not so severe as a study of Sherren's work led one to believe Nerve repair operations should he thought, be carried out by surgeons experienced in nerve surgery

Mr F M. **NICHOLLS** agreed that nerve repair should be placed in the category of major operations Some failures were attributable more to inexperience than to the anatomical conditions of the case

The **PRESIDENT** also emphasised the delicate problems which arose from injuries to nerves consequent on fractures In some cases many months were required to re-establish function.

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE tenth annual meeting of the Association of Clinical Pathologists was held at the British Postgraduate Medical School on Saturday Jan. 30th. The new president of the society Dr S C **DYKE** referred to the great loss sustained by the death of *Prof E H Kettle whose place as chairman of* the meeting was taken by Dr **JANET VAUGHAN**

Laboratory Diagnosis of Gonorrhœa

Dr G W **GOODHART** who opened the first discussion by a communication on the

DIAGNOSIS OF GONOCOCCAL INFECTION BY FILMS

said that there had been no important alteration in technique during the last 25 years most people now used some modification of the original Gram's method for staining but for the particular purpose under consideration there was still a good deal to be said for the older technique as it avoided the danger of over decolourising with alcohol. He had never departed from the admirable practice insisted upon in his early days by Prof Eyre of reporting only what he found and never saying that gonococci were present when from the nature of the investigation a definite bacteriological diagnosis was manifestly impossible Several workers had published figures to show the comparative value of smears and cultures in diagnosis. Everything depended on the material one was working with Most of the statistics came from workers in venereal disease clinics or from research departments. In the former there was a reasonable presumption that the material sent for examination came from a patient exposed to risk and in the latter optimal conditions for successful culture could be arranged Much of the work of the ordinary practising clinical pathologist had to be done under very different conditions Dr Goodhart's own views had undergone a complete change since he had been working in the hospitals of the London County Council, and he now regarded Gram negative cocci other than gonococci to be such frequent inhabitants of the urogenital tract as to make the diagnosis by film alone highly dangerous especially in vulvo vaginitis in children. Most workers who had investigated cultural results carefully had found a number of pseudo gonococci and the main purpose of his communication was to illustrate this point He then described ten cases from which he had isolated Gram negative cocci which from their cultural characteristics were clearly not gonococci according to prevailing views In some of these cases smears had shown typical Gram negative intracellular diplococci in others not even pus cells were present His experience suggested that it was often difficult to make an accurate diagnosis of gonococcal infection even by culture and that it was practically impossible by film alone

Dr **JOHN OLIVER** spoke on the

DIAGNOSIS OF GONORRHŒA BY CULTURE

He described two types of transparent culture medium for this purpose Hydrocele agar was best where this could be prepared without undue difficulty but the egg albumin medium of Price gave almost equally good results and was usually less difficult to make up Dr Oliver emphasised the need for immediate inoculation of exudates and the desirability of incubation without undue delay at temperatures lying between 35 5 C and 36 5 C The retention of moisture in the culture tubes was important for desiccation was the most important factor in the death of gonococci in swabs A replacement of some 8 or 10 per cent of atmosphere by CO_2 was of distinct advantage in the culture of gonococci Dr Oliver explained the oxidase reaction as a means of diagnosing the presence of gonococci in mixed cultures and finally discussed very briefly the fermentation reactions of the organism

COMPLEMENT FIXATION TEST

In the absence of Dr **ORPWOOD PRICE** on account of illness Dr **CUTHBERT DUKES** gave a brief account of Price's method of performing the complement fixation test and discussed the general significance of the reaction. It was important he said to bear in mind that this serum reaction does not show the presence or absence of gonococci in the tissues it only registers the presence or absence of gonococcal antibodies in the blood. The amount of such antibody might be expected to vary with the amount of toxin absorbed It was obvious that if the gonococcal lesion is open with plenty of opportunity for free drainage there is comparatively little opportunity for toxic absorption The fact that this condition existed in simple gonococcal urethritis explained why the complement fixation test remained negative for the first week or two of the disease. If the disease spread to the seminal vesicles the toxic products were unable to drain efficiently and in the presence of a closed infection antibody production increased rapidly Thus a positive gonococcal complement fixation test might be taken as evidence of present or immediately previous gonococcal infection but a negative test did not include the possibility of gonorrhœa The possibility of cross fixation with antibodies of allied bacteria such as the *Micrococcus catarrhalis* the meningococcus and *Micrococcus flavus* had often been raised and the evidence on this question has not been altogether conclusive Dr Orpwood Price had carried out a series of experiments in which he prepared antisera against the gonococcus, *Micrococcus catarrhalis* and *Micrococcus flavus* by injecting rabbits with those bacteria. The sera were then tested against gonococcal antigen in serial dilution ranging from 1 in 10 to 1 in 80 as for a complement-fixation test These experiments showed that a weak degree of cross fixation with the antibodies of

Micrococcus catarrhalis is liable to occur. Dr Dukes referred also to Dr Price's views on the gonococcal complement fixation reaction as a test of cure. As long as a patient had a persistently positive complement fixation test he should be regarded as infective and remain under medical supervision. When the test became negative after having previously been positive this in itself must not be taken as evidence of cure. In any test of cure both clinical and pathological examinations must be considered, and it was suggested by Price that if the patient showed no clinical signs or pathological evidence of the disease, normal life (with the exception of coitus) should be allowed for one month. Then the patient should be re examined and all tests repeated. If these still yielded negative results final tests should be made after a further month of normal life before the patient was regarded as cured. The gonococcal complement-fixation test was not a substitute for other criteria of cure but should always be supported by the results of smears and cultures.

A discussion on the

Diagnosis of Syphilis

was introduced by Dr J G **Greenfield** with a paper entitled

THE CEREBRO SPINAL FLUID IN NEUROSYPHILIS

He pointed out that the four reactions proposed by Nonne in 1909 still remain the most important for the examination of the cerebro spinal fluid in syphilis: the cell count, globulin estimation, Wassermann reaction in blood and cerebro spinal fluid, and a colloidal reaction. Dr Greenfield discussed these in turn and then took up the question of the cerebro spinal fluid at various stages of syphilis and its relation to treatment. In the secondary stages of syphilis meningeal reactions might occur in a small proportion of cases, but since the majority were not followed by neurosyphilis it seemed unnecessary to puncture patients before or during treatment unless there were clinical signs of syphilitic meningitis, in which case lumbar or cisternal puncture is a curative measure.

Only those cases in which meningeal reactions persisted into the latent period appeared likely to develop neurosyphilis, and therefore the best time to examine the cerebro spinal fluid in the earlier stages was a year after a complete course of treatment or at the end of the third year after infection. More frequent punctures during the secondary stage were not contra indicated, but the appearance and disappearance of meningeal reactions should not be allowed to influence treatment.

In the later stages a certain diagnostic and prognostic value attached to the rapidity with which the W R in the fluid cleared up under treatment and to variations in the Lange reaction. Although it was generally true that in meningovascular forms of neurosyphilis the W R in the fluid cleared up rapidly under treatment, there were many chronic cases of meningeal syphilis in which this rule did not hold good. In tabes and general paralysis the W R in the fluid was very stable and usually only weakened along with the weakening of the W R in the blood. But after malarial treatment in favourable cases the W R in the fluid might clear up fairly rapidly while the blood W R remained strong. In the latter type of case examination of the fluid at intervals was of definite prognostic value, and enabled relapses to be detected and treated at an early stage. Variations in the Lange reaction were also of value in prognosis, weakening of the reaction in a general paralytic after treatment with malaria or tryparsamide being usually of good omen, while a progressive strengthening of the reaction in cases of tabes or old standing syphilis pointed to the onset of general paralysis.

Dr H C **Lucey** read a short paper entitled Wassermann Snags in which he gave his experience of certain practical difficulties in the performance of this test and ways in which they might be overcome.

Dr A G **Signy** introduced a discussion on

CONGENITAL SYPHILIS

He described various methods for collection of reasonable specimens of blood from children: the puncture of the anterior fontanelle, of the external jugular vein, and of the internal jugular vein. He emphasised the importance, in testing the blood of children, of doing at least two types of tests—a recognised complement fixation as well as a recognised precipitation test. He discussed in detail the interpretation of the results of these tests, particularly the anomalous results occasionally met with. Before a diagnosis of syphilis is made from serological evidence alone the test must be repeated, especially in young infants who are quickly made negative on treatment. A provocative injection of arsenic was valuable when positive reactions were doubtful or weak. The histology of congenital syphilis was characteristic in many organs, especially the liver. Dr Signy discussed the anæmias of congenital syphilis and said that the children improved very rapidly in every respect under specific therapy.

Dr **David Nabarro** said that at the Hospital for Sick Children, Great Ormond street, more than half of the congenital syphilitic infants seen showed positive findings in their cerebro spinal fluids. As a rule this condition responded readily to the recognised treatment by injections, and in his experience the fluid which had once become negative very rarely relapsed. In most of these cases the neurosyphilis was latent, but sometimes there were signs or symptoms pointing to neurosyphilis, such as hydrocephalus, convulsions, and possibly mental retardation. In his view lumbar puncture should be carried out in every case of congenital syphilis in order to detect latent neurosyphilis, especially in rather older children, and to treat it, so as to prevent such untoward events as hemiplegias and meningovascular lesions leading to mental degeneration. In his experience the treatment of neurosyphilis in children with clinical manifestations was most disappointing, and on that account he strongly urged the routine lumbar puncture of all congenital syphilitics.

In reply to a question whether he had seen the symptoms in pregnant mothers diminish in intensity, Dr Nabarro said that most syphilitic mothers showed no signs or symptoms of the disease with the exception of a positive reaction in the blood. It had been stated that the blood reaction became negative during pregnancy, and this had been adduced as a reason for not doing routine blood tests on expectant mothers, and particularly those who attended antenatal clinics. In Dr Nabarro's experience the W R remained positive in pregnancy and often quite strongly positive, though in some cases it did diminish in intensity, doubtless owing to the treatment the mothers were having. During the last few months two infants had been brought to the clinic at Great Ormond street, both of them syphilitic, whose mothers had attended antenatal clinics during pregnancy, but had not been tested or treated. In his opinion every expectant mother should have a blood test

Demonstrations

In the afternoon the following demonstrations were given Dr E J KING demonstrated microchemical methods applied to capillary blood, for the estimation of sugar urea, uric acid, creatinine and chloride.—Dr JOHN GRAY illustrated by museum specimens and histological slides the main types of Bright's disease —Dr JANET VAUGHAN demonstrated material obtained from sternal marrow puncture in the following cases: (1) normal marrow (2) Addisonian pernicious anæmia (3) myelomatosis (2 cases) (4) secondary carcinomatosis In the three last cases the biopsy had enabled a correct diagnosis to be made. She also described the technique employed and the type of instruments used.—Dr A A MILES and Dr J GRAY demonstrated the post mortem and bacteriological findings in two cases of endocarditis due to infection with organisms provisionally identified as *Hæmophilus influenzæ* The main interest lay in the organisms isolated which corresponded closely with strains isolated in the last few years from similar cases Dr Miles and Dr Gray showed the cultural and biochemical characters of the organisms a rapid bacteriological test for a preliminary differentiation of these organisms from true influenza organisms and an important fallacy in the preparation of yeast extract, peptone water and sugars

MEDICAL WOMEN'S FEDERATION

AT a meeting of the London Association held on Jan. 26th Miss E C LEWIS the president being in the chair Dr ANDREW TOPPING spoke on the

Modern Treatment of Fevers

Scarlet fever he said, was the commonest of the acute exanthemata, but it presented great difficulties to the administrator In the early days of fever hospitals many hoped that the incidence would be reduced The mortality had been lessened and for the past thirty years the illness had been extremely mild but the question now had to be faced: should patients be treated in hospital? Scarlet fever was one manifestation of streptococcal infection probably many of the 28 recognised kinds of streptococci might cause it in some cases and (say) streptococcal throat infection in others isolation of scarlet fever patients could not prevent other cases occurring and some undoubtedly became infected with other strains while in hospital. The one big modern innovation in treatment was the use of antitoxin Nowadays every serious case received it and in some hospitals every case however mild the illness was cut short by it desquamation did not occur there were fewer sequelæ Prontosil first used in Japan and then in Germany was the one drug available which showed promise of being effective against several kinds of streptococci.

In measles convalescent serum had no curative value Intensive treatment with vitamins A and D had been tried out by Dr Helen Mackay who had reluctantly come to the conclusion that it made no difference Eye and ear consultants should be called in early to eye and ear cases before the conditions were firmly established The London County Council were setting up country homes for these cases so that they might lead a more normal convalescence Whooping-cough cases seemed to be free from ear complications and it was thought that if the children laughed ran about and coughed the pharynx was kept clearer and the ears recovered more quickly Oxygen had proved very useful for pneumonia the L C C had twenty tents in use and planned to have twice as many before the next epidemic expected, he believed, to start on Nov 14th Undoubtedly patients with whooping-cough should be granted admission to hospital much more readily than they were The difficulty was to convince parents and local councillors of the fact that children were not infectious for more than a fortnight after developing the whoop Treatment had been attempted with cow serum. Direct plates revealed the bacillus a month or six weeks after the whoop had appeared but that was not evidence of infectivity; probably a virus was either necessary for the invasion by the bacillus or else was the causal agent itself. Probably Luminal sodium was the best drug but its dose had to be adjusted with great care according to the child's weight drowsiness must be avoided.

Diphtheria could be stamped out by an efficient immunising campaign The principal causes of failure in its treatment were failure to recognise the condition reluctance to admit the diagnosis and reliance on swabs It was axiomatic that the death rate varied inversely with the length of time between the onset of the illness and the giving of a sufficient dose of antitoxin The size of the first dose was of great importance work done all over the world had shown that the toxin once fixed in the tissues was impervious to antitoxin The gravity of each case had first to be assessed: whether it was the first second, or third day and whether there was marked toxæmia. Sixteen thousand units were enough for mild cases but where there was smell bull neck, or the likelihood of marked toxæmia 60 000 to 100 000 units should be given intravenously immediately A booklet issued by the L C C. (price 3*d*)[1] gave full details of the technique. Intubation had supplanted tracheotomy in most instances The Drinker respirator although a cumbersome apparatus was giving almost uniformly good results in the treatment of diaphragmatic paralysis

Cerebro spinal fever was now diagnosed more satisfactorily by blood culture than by examination of the cerebro-spinal fluid by the latter method a mild or fulminating case might be missed while blood culture gave a positive result in almost every case. The modern treatment was to insert a special lumbar puncture needle and to leave it there to allow a continuous drip of cerebro spinal fluid Antitoxin was given into the blood stream.

In America vaccination against small pox was now being carried out by intradermal injection with good results He felt there was no evidence that the present mild form of small pox would breed true He had seen one confluent case whose only apparent contact had been an ordinary mild one

THE PROPHYLACTIC ASPECT

Dr E ASHWORTH UNDERWOOD said that attempts at producing immunity had been made many centuries ago when physicians exposed their patients to diseases in the hope that they would catch a mild form of them Jenner's inquiries were the first scientific step towards specific prophylaxis Of the five principal diseases against which artificial immunity was being tried here diphtheria was so far the most favourable At the time when the Medical Research Council published a monograph on it in 1923 many people had felt confident that the use of antitoxin could keep the mortality down to the low figure of about 4 per cent Then reports from Berlin and

---

[1] See *Lancet* 1936 2 1187

Budapest of more frequent severe cases caused disquiet and about five years ago such cases became common in this country The Schick test was the most reliable guide to individual immunity In using it the full dose had to enter the arm, preferably into the skin, but the speaker was not convinced that if some of the fluid went into the subcutaneous tissues the result was altered Pseudo reactions were not so common as they had been seven years ago They were commonly held to be detectable on the fourth day but he thought the test should be repeated when doubtful. The Moloney test consisted in observing the reaction produced to the intradermal injection of dilute toxoid, the reactions resembled those of the Schick test A positive result denoted sensitisation of the individual by the products of the diphtheria bacillus and had been obtained in 80 per cent of his cases who reacted strongly to toxoid treatment

The first method of immunisation used was injection of toxin fully neutralised with antitoxin, but the danger of freezing or faulty mixing setting free unneutralised toxin caused the method to be given up It was succeeded by toxoid antitoxin mixture (T.A M) which the speaker thought should now go into honourable retirement Among its successors were formol toxoid, alum toxoid (formol toxoid precipitated by alum and acting over a long period because of its insolubility), and toxoid antitoxin floccules (T.A F) The first two were apt to cause reactions but acted relatively quickly, the third was undoubtedly the simplest and most innocuous prophylactic known, but it was somewhat slow The relative advantages of one and multiple shot methods had been much discussed, if the resulting immunity were compared, two or three shots would always win The speaker showed by graphs how incidence and death rate fell with a rising proportion of the population immunised He considered that at least 30 per cent of pre school children should be treated to keep the disease in check.

Immunity to scarlet fever was not so satisfactory Five doses were necessary and then apparently only protected against erythema and not against invasion, the patient might still go about with a streptococcal infection of the throat

Two types of serum were in use for protection against measles, the convalescent type obtained from patients between the seventh and tenth days of illness, and the adult serum from healthy people who had had measles Protection could be conferred for a few weeks by either type if given within six days of exposure, attenuation could be achieved by a full dose given later or by a half dose within the six days The modified attack gave immunity for life

In reply to a question from Dr D McNair about a Schick reaction appearing on the sixth day, Dr Underwood said that a delayed reaction was recognised.—Miss G M Sandes asked about the use of placental extract in the treatment of measles, to which Dr Underwood answered that he thought it had not been a great success —In reply to Dr A F Judd, he said measles serum was procurable from Messrs Burroughs Wellcome, it had to be stored on ice In practice 10 c cm. of parental blood given into the child's buttock would prevent or attenuate the illness

Dr Ursula Blackwell, in moving a vote of thanks to the speakers, mentioned that her experience at a fever hospital confirmed what Dr Underwood had said

MEDICAL SOCIETY OF LONDON

At the meeting of this society on Feb 8th, with Sir William Willcox, the president, in the chair, a discussion took place on

Treatment of Facial Paralysis

Dr Macdonald Critchley, in opening, said that to the neurologist the treatment of this condition could usually be summarised as consisting of massage, electrical treatment, and the use of a facial splint But the end results were found to differ in spite of a similarity in the treatment adopted. Traditionally Bell's palsy was described as an acute inflammatory swelling of the nerve trunk and its interstitial tissue as a result of exposure to cold, with resulting strangulation of the nerve by the bony walls of the Fallopian canal. Probably these assumptions were incorrect in most cases of Bell's palsy, since very often there was no supporting history, and in any case it was not clear why only one side should be affected—a main feature of the condition The late James Collier and others taught that a proportion of cases of Bell's palsy were due to a neuro fixating virus, as in the facial palsy from known neurotropic virus disorders, such as tetanus and rabies R S Aitken and R. T Brain had found, by means of the complement-fixation test of Bedson and Bland, that in some cases (4 out of 22) the blood serum contained antibodies to herpes zoster, showing that Bell's palsy was sometimes a virus disease It would be interesting to know how often the conditions were related. Dr Critchley thought it safest in the present state of knowledge to regard Bell's palsy as a mere symptom with probably several causes Good end results were obtained in 80–85 per cent of all cases, if the rest had any special features these would be valuable in prognosis A Tumarkin had suggested that pain and loss of taste gave a grave prognosis in the early stages, without them the patient had a 25 to 1 chance of recovery of function Dr Critchley's experience of cases with known ætiology suggested that most of those with the Gowers Hunt syndrome did badly, while other instances of virus affections soon made an excellent recovery Much sagging of the face from permanent atonic paralysis proclaimed failure of treatment, but early use of a facial splint, with more vigorous electrical stimulation would probably have prevented this When such a deformity was established, he assumed that plastic surgery offered the only alleviation In the course of recovery there might occur spontaneous facial twitchings to be treated with a partial ablation of the nerve function by a minute injection of alcohol. Tonic facial spasm was a very common sequel, but it needed treatment only when extreme and deforming, this consisted of massage and manual stretching of the muscles that were contracted Facial synkinesia often developed, and might be embarrassing Finally, Dr Critchley asked how acute cases of Bell's palsy might be treated in which no good end result seemed likely from electrical testing and on clinical grounds.

OPERATIONS

Sir Harold Gillies described the use of the temporal muscle as a fake mover of the face Plastic operations, he said, were indifferent palliatives in comparison with what he hoped the nerve grafting and decompressing operations would produce The time for the plastic surgeon to intervene was when the face was completely unresponsive or "dead", indeed, he felt that his own usual function was that of facial undertaker The facial slings which were put in to grip the muscles were surgical splints and more efficient than the usual mechanical aids; they might prevent in some cases, over stimulation by electrical practitioners of a muscle that was already knocked out. The operation was simple the complications were not serious, and if in spite of the bad prognosis the nerve should happen to recover the bands would have done nothing but accelerate recovery Patients thus treated were perhaps the most grateful of those he met for anything done to improve their appearance definite mental trouble sometimes supervened. The operation, which he demonstrated with a film added the temporal muscle s movement to the sling and the patients could afterwards use the biting grip and move the face.

Mr **Terence Cawthorne** speaking on nerve grafting said that until recently the most favoured operation was anastomosis in the neck and remote from the site of injury in the temporal bone of the distal end of a divided facial nerve with the central end of some neighbouring nerve. The results showed however that a satisfactory return of facial movements could only be expected by exposing the nerve at the site of injury and by restoring anatomical continuity Relief of compression or restoration of continuity between the divided ends, either by direct apposition or a homogenous nerve graft were the methods of choice. To ensure the best functional results the affected nerve should be exposed as soon as practicable In mastoid operations the facial nerve was very vulnerable and easily damaged by curette or gouge by a fracture fragment from the bony canal, or when exposed, by bruising with instruments or gauze swabs The best guide to the severity of the injury was the length of time between the operation and the onset of the paralysis If this was short, it was certain that the injury to the nerve was severe, and surgical exploration of the nerve should be carried out as soon as the patient s condition would admit. This was important as the degree of recovery after the facial nerve grafting depended largely on the interval between the injury and its repair Failure to recover at the end of a month should lead to a consideration of operation especially if the nerve trunk did not respond to the faradic current.

The first step was to expose the nerve at the site of injury this would enable the surgeon to know whether and what treatment was needed to restore continuity To bridge the nerve gap Ballance and Duel—to whom Mr Cawthorne paid a tribute for their pioneer work—had shown that the only material worthy to be considered was a piece of living nerve usually taken from the intermediate cutaneous nerve of the thigh being cut and allowed to degenerate in situ for two or three weeks The results had been remarkably good In facial palsy not due to trauma that associated with suppurative ear disease was important If otitis media was of long standing extension of the disease to the facial canal and perhaps to the labyrinth must be borne in mind then a radical mastoid operation with thorough removal of the diseased bone was called for Generally however there was no obvious local injury or disease and these cases were styled Bell s palsy It was the rule for these to clear up spontaneously He described the technique of nerve exposure and repair operations and showed a film.

Mr **Dickson Wright** said he had had to deal as a surgeon with many cases of facial paralysis They resolved themselves into medical and surgical types In the former Bell's palsy Dr Critchley had suggested that the idea of a swelling of the nerve might not be tenable, but the reply was that good results had followed decompression of the nerve The Ballance Duel operation was useless in facial clonic spasm and in some cases arising from fracture of the base He agreed that the operation illustrated by Sir Harold Gillies was best in cases of dead face in which the muscles showed no sign of recovery Mr Cawthorne had considered that when all galvanic response had disappeared no attempt should be made on the nerve but he himself had had a case of a withered arm after injury to the brachial plexus Amputation was discussed but it was deferred when some time later the muscles of the arm began to show a return of power He concluded with a film on the operation of hypoglossal facial anastomosis

Mr **Cecil P G Wakeley** said he had worked on this subject with the late Sir Charles Ballance for ten years and they did together 14 cases of hypoglossal facial anastomosis in 12 of which the results were quite good. In some of their later cases only half the split hypoglossal nerve was used and the results were as good as when the whole nerve was employed. The ensuing paralysis of the tongue was minimal.

DISCUSSION

Sir **Harold Gillies** referring to the Ballance Duel operation asked whether Mr Cawthorne thought a nerve graft could be put with impunity into a pool of pus as in a suppurating mastoid cavity He knew of no other graft which would live in such conditions.—Mr **Donald Wheeler** agreed that in acute mastoid cases the grafting during the process of suppuration was futile in such circumstances he had not known a case do good.—Mr **G H Livingstone** said he had helped Prof Duel with one of his cases of grafting in which there had been no result for nine months, after which recovery had been progressive —Mr **Harold Kisch** said he had operated upon four such patients but two were too recent to speak of yet. The other two were successful the first being in a child aged two after 6 months the second a woman aged 23 after 18 months

Dr **Critchley** in reply said he was not yet clear about the absolute indications for operation in Bell s palsy He was aware that loss of faradic response persisting to the end of the second week could be taken as an indication but he doubted if this were true He had hoped that someone skilled in electrotherapy would have given enlightenment on this point. There were cases showing true reaction of degeneration at the end of the second week which yet made a good recovery and not all those who gave a faradic response at the end of the first fortnight made a perfect recovery Should such patients be sent to the electrotherapeutic department or to the surgeon for decompression?

Sir **Harold Gillies** said his feelings to night were very much towards the medical side and he felt that the profession was still without the clear indication that Dr Critchley desired. Most mastoid operators would say that most of their cases of facial paralysis showed some recovery in a period ranging from three months to two years His electrotherapeutic colleague had said that a loss of faradic response at the end of ten days betokened severe injury to the nerve and he gave a guarded prognosis for he expected that recovery would not at all events be complete

REVIEWS AND NOTICES OF BOOKS

Clinical Use of Digitalis

By DREW LUTEN, A B , M D , Associate Professor of Clinical Medicine in the Washington University School of Medicine London Baillière, Tindall and Cox. 1936 Pp 226 16s

DIGITALIS is one of the most valuable drugs we have—the statement has remained unchallenged through innumerable editions of "Hale White"—but its value to the clinician is directly proportional *to his knowledge of its properties and the indications* for its use The embodiment in book form of the well known work of Dr Luten on the clinical use of digitalis is therefore an event to be welcomed. After considering the mode and sites of action of the drug on the myocardium, the author arrives at the conclusion that the chief and only important action of digitalis is to increase the efficiency of the contraction in the presence of heart failure This belief—that digitalis is to be used in the presence of heart failure, or impending failure, and then only—is the pivot of the whole book, and one against which few valid objections can be brought For twenty-five years it has been taught that digitalis has its most dramatic effect when used for heart failure associated with auricular fibrillation and a rapid ventricle, while this is probably correct, Dr Luten emphasises the secondary importance of the rhythm and the rate, the all important factor being failure In other words its effects are displayed irrespective of the rhythm and rate and its administration is rarely justified for these disorders alone Dr Luten believes that digitalis only reduces the ventricular rate in fibrillation when some failure is also present, and from this he concludes that if slowing does result it is largely a secondary effect of improved myocardial efficiency This view is supported by the observation that digitalis does not slow the heart-rate in fibrillation associated with toxæmias and infections in the absence of failure

The second half of the book is devoted to the indications for the use of digitalis in certain special situations, it is in effect *an amplification* of the guiding principle that digitalis is called for in cardiac insufficiency The complexities of dosage and administration are dealt with in full detail If the methods and principles here so clearly exposed were generally followed there would be some reduction in the number of patients who are treated with digitalis, and a fuller and safer effect in those to whom it is given Dr Luten's monograph can be recommended as a sound contribution to modern therapeutics

Comparative Anatomy

By HERBERT V NEAL Professor of Zoology, Tufts College, and HERBERT W RAND, Associate Professor of Zoology, Harvard University London H K Lewis and Co, Ltd. 1936 Pp 739 21s

THIS book is intended in particular for the medical student, so that the detailed information which T H Huxley regarded as appropriate to a text book on comparative anatomy gives way *to a more general* systematic treatment, in fact the work is morphological rather than anatomical. It is written in an interesting way and is well illustrated We cannot accept without protest the authors' assumption that the student is not interested in morphological problems, most students take an interest in such questions when the bearing on human structure and variation is made evident to them This book deserves a successful future, although the differences between the curriculum in the United States and in this country may perhaps affect its popularity here In any case it is a book which the more thoughtful student will enjoy

The Development of Modern Medicine

By RICHARD HARRISON SHRYOCK, Professor of History, Duke University, Philadelphia London Humphrey Milford, Oxford University Press 1936 Pp 442 18s

THE medical profession have certainly, to day, large opportunities for learning the history of their science, the part played by the path finders, and the personality of the pioneers American authors have been particularly industrious, and we now look to America for the best expositions of medical history Prof Shryock writes on a new and interesting pattern. He makes no attempt to study the technical history of medicine but portrays the more important aspects of medical development seen against a background of social history in general, as a contribution to which it makes extremely interesting reading The story commences with the seventeenth century and the usual chapters on the old Greek and Latin observers are omitted, probably to the relief of many We start with descriptions of the early work in the medical centres of France, Germany, England, and America, and throughout the intention is sustained to show the part which medicine, as it progressed, played in the reforms of changing society The author's thesis is that the happiness and progress of a people must bear definite relations to the status of medical science in the country and to the extent to which medical advance is employed for the public good.

Of the medical science of the eighteenth century the author, being fully read and documented before forming his opinion, has no complimentary picture to draw The physics of the day were not adaptable to therapeutics and medieval credulity and a slavish following of tradition were everywhere in evidence By the end of the eighteenth century the position was changed and a great improvement in scientific methods was manifested, but this did not mean the scrapping of all the old superstitions, for many familiar and popular conceptions were *found*, on closer examination, to be capable of development into valuable therapeutics An interesting chapter summarises the early contributions of medicine to the public welfare of the eighteenth century, while the first half of the nineteenth century witnessed developments which must sometimes have been impeded or obscured by the direction of thought throughout a romantic age But the relations between medicine, the basic social sciences, and mathematics began to show a convergence which led to fundamental changes. These are exemplified in sections which follow on the influence of modern medicine in France and Germany, but throughout the early part of the nineteenth century there was little scientific progress made for the promotion of public health. Prof. Shryock evidently regards as the chief British contribution to medicine at the period the development in public health movements The result, he says, was that the health programme entered a new phase after 1870, so impressive a phase that it was soon viewed as the very beginning of things in public hygiene with perhaps a tendency to exaggerate the value of medical research.

The book is largely written from the American standpoint and the last chapters, which describe American views upon national health insurance and record some pertinent statistics deserve close attention. There is as yet no general approval of national health insurance in the United States but the efforts of those who believe that legislation with some such object is necessary are recorded by Prof. Shryock with informing detail.

This is a good book.

Starling's Principles of Human Physiology

Seventh edition. By C. Lovatt Evans, D.Sc., F.R.C.P., F.R.S., LL.D., Jodrell Professor of Physiology in University College, London. The chapters on the central nervous system and sense organs revised by H. Hartridge, M.A., M.D., Sc.D., F.R.S., Professor of Physiology at St. Bartholomew's Medical College. London: J. and A. Churchill Ltd. 1936. Pp. 1096. 24*s*.

When E. H. Starling wrote the first edition of this book twenty-four years ago he cannot have foreseen the burden of knowledge it carries to-day. We use the word burden advisedly. Physiology was then being conquered by physical and chemical methods and although we cannot surmise what Starling thought he would have been justified in supposing that a quarter of a century would find the subject perhaps greatly extended but simpler to expound. As it is physical and chemical methods greatly refined have served but to reveal an infinite complexity easy to evade in an elementary treatise but very difficult to deal with in an authoritative work. English physiology owes a great debt to the present author of Starling's Physiology. In the midst of a flood of books on specialised branches of the subject, on its more advanced aspects and on physiology for medical students for nurses, and for the general public, he has not shirked the task of maintaining the standard and tradition of a book whose title might well be simply Physiology so well does it epitomise all we understand by that term.

The size of the book somewhat reduced in this edition may seem forbidding to the student but it contains all the biophysics and biochemistry he needs and has an exhaustive section from the pen of Prof. Hartridge on the special senses. The serious student will turn to this book because it deals in a satisfying manner with the strictly scientific aspects of the subject and yet gives a living account of the living body. Where it is difficult to formulate a conclusion the evidence is discussed, instead of the nearest or most probable approximation to the truth being baldly presented. This makes it more difficult to learn but easier to understand and of great educational value. The references to original papers in footnotes and to monographs and other books given at the end of each chapter are of inestimable worth and serve still further to enhance the vitality of the book. The vitamins the ductless glands and the humoral transmission of nerve impulses come in for special treatment in this edition, as was to be expected. The nervous system is perhaps the least satisfactory section more from the point of view of arrangement than from any sins of omission. The plan followed by Prof. Hartridge in presenting it is in a way logical but he should consider whether it is justifiable on practical grounds to start with the cerebral hemispheres and finish with the spinal cord. The elimination of the purely anatomical sections on the central nervous system is an improvement.

The new edition has been conscientiously revised throughout many old illustrations dropped and better ones introduced the publishers are to be congratulated on the excellence of their plates. The freer use of heavy type for subheadings is another commendable feature in its production. In spite of the increasing difficulty of the subject the book remains more firmly entrenched than ever in the position intended for it by Starling.

Bell's Sale of Food and Drugs

Ninth edition. By R. A. Robinson, of the Middle Temple, Chief Officer Public Control Department Middlesex County Council. London: Butterworth and Co. Ltd. 1937. Pp. 321. 15*s*.

This well-known legal text-book has long been popular with health officers because of its lucidity reasonable size and excellent indexes. The eighth edition was published after the Food and Drugs (Adulteration) Act of 1928 came into force and since then the sale of food and drugs has not altered much. But the Milk Act of 1934 and amended orders have materially changed the sale of milk and new orders under the Merchandise Marks Act of 1926 have affected the powers and duties of local authorities. The whole text has now been revised, although the body of the book remains the same in form. The sections on milk have however been rewritten and as it is for guidance in the confusing legislation of milk sale that Bell is most frequently consulted by medical officers the ninth edition is for them practically a new work. Some points in the law relating to milk are unfortunately still obscure and in the absence of rulings remain doubtful. Measures to be taken against adulteration were covered by the Act of 1875 and the orders based on it and were incorporated in the Act of 1928. They give the medical officer of health little trouble but the milk orders give him as much worry as any of his work and he is often in doubt about his duties. So an up-to-date edition of Bell is a comforting guide to have on his desk.

Practical Preparations Mainly Medical

By N. W. Powell, late Sister Hope, St. Bartholomew's Hospital. Second edition revised by P. Gill, late Sister Tutor the Royal Free Hospital. London: Faber and Faber Ltd. 1936. Pp. 212. 3*s*. 6*d*.

This pocket-size manual describes the nurse's part in preparing for and helping with the various diagnostic and therapeutic procedures and includes the technique of such things as simple urine testing and collecting vaccination and catheterisation which a nurse may be called upon to carry out. Where necessary enough explanation of the purpose and rationale of any particular procedure is given to enable the nurse to act intelligently. The technique of hypodermic injection was presumably regarded as too simple to warrant description yet whether this is done neatly or clumsily makes a real difference to the comfort of a sensitive patient and there is a note on how to perform the last offices still curiously enough regarded as part of a nurse's job though many may think that her time might be spent more profitably with the quick than with the dead Nevertheless this is a practical little book which should be of use to those engaged in both institutional and private nursing It includes a detailed but concise account of the special diets employed in certain diseases and there is an index

Les avortements mortels

By H Mondor, Professeur agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital, Bichat Paris Masson et Cie 1936 Pp 445 Frs 65

The importance of abortion as a cause of maternal mortality is well recognised. This book is concerned with the fatal acute complications of abortion and discusses them fully from their ætiological, pathological, and clinical aspects An extensive bibliography adds to the value of the volume, though there are minor inaccuracies, and it is perhaps not fully representative of the literature The section on anaerobic organisms in relation to post abortion infections is particularly interesting The author is a strong supporter of radical measures in treatment Colpotomy and hysterectomy with or without drainage are advocated in peritonitis and septicæmia In the latter condition he places great reliance on confirmation of a positive blood culture and evidence of hæmolysis as guides to the necessity of operation

The book is pleasant to read, the more so as Prof Mondor constantly illustrates his views by clinical excerpts from his own case records

Methods of Tissue Culture in Vitro

By Ralph Buchsbaum, Ph.D, Department of Zoology, University of Chicago, and *Outlines of Histological Methods with Special Reference to Tissue Culture* by Clayton G Loosli, Ph D, Department of Anatomy, University of Chicago London Cambridge University Press 1936 Pp 81 4*s* 6*d*.

The first part of this book is intended to present a simplified method of tissue culture for a single investigator in an ordinary biological laboratory It begins with a statement of the general principles of tissue culture and proceeds to a full description of how to arrange and equip the laboratory and how to organise the routine work. Asepsis, the preparation of media, and finally the preparation of cultures are considered in great detail. A useful summary of the apparatus required for a tissue culture laboratory is appended The second part outlines methods for fixing, embedding, sectioning, and staining cultures and control tissues One important point of technique has perhaps hardly been sufficiently stressed. The reader is advised not to prepare plasma "less often than once every week or two," and tissue extract if possible once a week. To get the best results we have no doubt *that the plasma used* should not have been as much as a week in cold storage, and for many types of culture it is undesirable to keep tissue extract for longer than 24 hours

The book, which is written in a clear and logical manner, is by no means a complete account of tissue culture methods, several important techniques being omitted. Its special value lies in the fact that both the tissue culture and histological methods described are mainly those used in the laboratory founded by the late A. A Maximow, now directed by Prof. W Bloom, and for this reason the book will be welcome in all tissue culture laboratories.

Quarterly Journal of Medicine

The January number (Vol 6, No 21) contains the following papers

A Study of the Choline Esterase Activity in Nervous and Mental Disorders By Henry Tod and M S Jones (Royal Edinburgh Hospital) Values obtained by the authors' method in 203 patients and 30 controls are summarised The esterase activity in the serum is high in anxiety states, low in catatonic stupor and epilepsy, and not abnormal in hysteria, melancholia, mania, paranoia and paraphrenia, and thyrotoxic states

The Fate of Large Doses of Iron Administered by Mouth By John Fleming Brock and Donald Hunter (British Postgraduate Medical School and London Hospital) Accurate balance experiments show that in normal subjects approximately 10 per cent of the iron given by mouth as Blaud's pill (90 grains daily) or iron and ammonium citrate (80–120 grains daily) is retained in the body In patients with hypochromic "iron deficiency" anæmia the retention varies from 11 to 32 per cent, and sometimes far exceeds the iron equivalent of the increase of hæmoglobin in the blood

Acromegaly and Creatine Creatinine Metabolism. By I Schrire (National Hospital for Nervous Diseases, London) In nine cases of acromegaly the urinary output of both creatine and creatinine is shown to be abnormally great and abnormally variable from day to day Injection of thyreotropic hormone in normal subjects increases creatine output (as do thyroid and thyroxin) Injection of "antuitrin" (Parke, Davis's anterior pituitary extract, without thyreotropic activity) in normal subjects increases creatinine output Probably, therefore, an eosinophil adenoma secretes an excess of thyreotropic hormone, affecting creatine, and of another hormone affecting creatinine

Observations on Agranulocytosis By M C G Israëls and John F Wilkinson (Manchester) Five cases of agranulocytosis and one of chronic neutropenia are described Two of the former were attributable to amidopyrin, and amidopyrin sensitivity was demonstrated in one of them Bone marrow examined post mortem contained very few granular leucocytes, myelocytes, or pro myelocytes Pentnucleotide was given to five patients, but in only one could it be credited with a possible beneficial effect

The Prognosis following Recovery from Coronary Thrombosis, with Special Reference to the Influence of Hypertension and Cardiac Enlargement By J H Palmer (London Hospital) An elaborate analysis of the records of 212 patients who have survived coronary thrombosis by more than three months More than a fourth are able to lead fairly active lives The rest lead restricted lives, on account of angina of effort, dyspnœa on exertion, or congestive failure, or they have died The presence or absence of hypertension gives no indication of a patient's expected duration of life, his liability to further coronary attacks, or his prospect of being fairly active On the other hand, patients with normal sized hearts are somewhat more likely than those with enlarged hearts to live longer, to remain active, and to escape subsequent coronary attacks, they suffer from angina to the same average degree as the others, but they do not develop congestive failure

The Heart in Emphysema By John Parkinson and Clifford Hoyle (London Hospital) A clinical study of 80 patients Emphysema causes enlargement of the pulmonary arteries, the conus of the right ventricle, the right ventricle, and the right auricle, in that order of progression and therefore of frequency Radiological evidence of these changes is found in about half of the cases Emphysema alone rarely causes congestive failure, but failure so caused is severe and usually fatal Emphysema is often associated with systemic hypertension or other conditions affecting the heart these are responsible for left ventricle enlargement, which is often found, and for most cases of congestive failure

The Magnesium Content of the Serum in Renal Insufficiency By Ronald W Brookfield (Liverpool) It is raised, up to twice the normal value, in acute and chronic glomerulo nephritis and other conditions causing renal insufficiency and nitrogen retention Calcium content tends to vary inversely Magnesium sulphate, *in normal doses by mouth raises the serum magnesium level* comparatively little even in patients with renal insufficiency

THE LANCET

LONDON SATURDAY FEBRUARY 13, 1937

THE LIMITATIONS OF HEARING AIDS

SINCE the invention of the telephone which it may be recalled was devised by BELL originally as a hearing-aid for the deaf scientific study of the reproduction and amplification of sound has become more and more important commercially and has in consequence made rapid progress Hearing-aids too have been greatly improved during recent years but further improvement is still possible and the report of investigations made by Dr and Mrs EWING and Dr LITTLER which was summarised in our columns last week, contains many conclusions of interest in this respect An important section deals with auditory fatigue This is observed with normal subjects as the result of stimulation by pure tones maintained at large intensities for two or more minutes but deaf subjects appear to be less susceptible auditory fatigue is not however experienced after listening to loudly amplified speech because the duration of the loudest components of this is never greater than half a second Daily use of a powerful hearing aid over a prolonged period has not been followed by any change in auditory acuity This disposes of the objection often raised by patients who dread that the use of a hearing aid may damage the remains of their hearing Experiments were made on the intensity level at which speech was *most clearly intelligible* for listeners with unimpaired hearing syllables were recognised with an accuracy of 70 per cent at a loudness of only 30 decibels above the normal threshold of audibility the equivalent of a whisper at 15 inches from the ear but with an accuracy approaching 100 per cent when its loudness was raised to 70 decibels above the threshold corresponding to an *ff* voice at 8 feet an increase of intensity to 110 decibels caused a slight loss of intelligibility Although a high degree of intelligibility can sometimes be obtained with deaf subjects this is not always possible even with the best available microphone and amplifier system 100 per cent. intelligibility cannot be obtained with any deaf subject using the simple non valve types of electrical aids This failure is probably due to the relatively low intensity of the consonant components of speech which may not reach above the subject s threshold of hearing all deaf people seem to find it easier to distinguish vowels than consonants With the most severely deaf patients an intensity level of 110 decibels was necessary and even then 100 per cent accuracy could not be obtained higher levels could not be used owing to the disagreeable sensations produced when the threshold of feeling was approached (An intensity level of 110 decibels is that of an aeroplane engine quite close to the listener s ear) This threshold of feeling places a limit on the degree of amplification permissible especially for nerve-deaf patients in whom it appears to be unduly low such a patient may have a maximum intelligibility at 90 decibels but be unable to bear a loudness above 100 decibels If his hearing aid is adjusted to give maximum efficiency for quiet speech it will be detrimental when used for listening to sounds only 10 decibels louder The authors do not mention an automatic volume control which was introduced to meet this difficulty and noticed in our columns last year[1]

The most satisfactory results with every subject were obtained by that hearing aid which has the nearest approach to uniform amplification over the frequency range of *from 200 to 8000 double vibrations to obtain* which valve amplification is at present indispensable Another important if depressing conclusion is drawn from these studies that until amplification of a higher order than has as yet been achieved can be secured over the whole speech range, tests of the possibility of matching an aid to a hearing loss curve are not feasible and claims that this matching can be done with small aids are premature The authors find also, that portable non valve battery aids are seriously handicapped by their uneven frequency response and by their low amplification factor their efficiency is greatly affected by changes in the distance between speaker and microphone, and sound reproduction is lacking in natural quality Bone-conduction receivers are found to have a range of intensity considerably less than that of an efficient air-conduction receiver and to be an uneconomical means of using the output of an amplifier It seems to us that the authors somewhat underestimate the practical value of these small aids to the numerous class of moderately deaf people Their experience has largely been among very deaf children and of the eight other patients on whom tests were made the least afflicted was so deaf that *mf* conversation was to him 10 decibels quieter than a whisper would be to a normal listener

The conclusion reached is that the conditions under which hearing aids are supplied to the public should include tests of the patient s response to pure tones by the audiometer and a standardised articulation test with the instrument which it is proposed to supply for a period of trial The tests of audibility of speech were made in this investigation on an apparatus assembled inside a soundproof room with a meter to indicate the output level and to assist the speaker to maintain a constant loudness which was then controlled by an attenuator Tests of this nature cannot in practice be demanded of commercial firms who supply hearing aids and it is therefore fortunate that in the present study the results obtained by testing patients for a series of pure tones by means of the audiometer provided a reliable index of the intelligibility of speech to the deaf listener It is important to remember that the intelligibility of speech heard through the best hearing aid is seriously diminished if the acoustic properties of the room are poor, if the speaker talks with a non-resonant voice, and if extraneous noises or general conversation complicates the sound intended to be heard

---

[1] *Lancet* 1936 1 1163

On the outstanding work standing to the credit of Dr and Mrs EWING and their collaborators on the use of hearing aids in the education of deaf children we have already commented[2] In their experience the class amplifier has many advantages over individual aids Four special classes have received daily systematic teaching by combined hearing and lip reading since September, 1935, the rate of progress obtained in speech and general school work, compared with the previous results of older methods, is even more satisfactory than was expected Reproduction of the highest quality is even more important to the severely deaf child who is dumb or retarded in speech than to the adult Examination of the hearing of backward children is of great moment, for, of 27 children from schools for the mentally retarded, only 3 were found to be mentally affected, 24 being deaf and therefore unable to understand ordinary class instruction

MENTAL DISEASE IN LONDON

THE mental health services of the London County Council are so extensive—they are concerned with approximately twice as many patients as are those of the whole of Scotland—that an annual report[3] can give only a summary of changes, statistics, and research Among the changes last year was increased provision of beds, so that there were 155 more in the ten large mental hospitals, giving them accommodation for 21,472 patients, actually they can hold even more than this A substantial increase also occurred in the proportion of voluntary patients, this was much more evident in some mental hospitals than in others In the various districts of London the permissive "voluntary" clauses of the Mental Treatment Act were for some reason more used south of the Thames, where about a quarter of those referred to a mental hospital were thus enabled to escape certification Such a discrepancy between particular areas may be due in part to the authorities in observation wards having widely different views of their responsibility and powers in regard to voluntary treatment, another factor is, no doubt, the willingness of patients to go to a particular mental hospital which usually receives people from their district It would be an advantage if those hospitals which —mainly for historical or architectural reasons— are unpopular with the public could come to have as large a number as possible of their patients transferred to the voluntary class, it would help to mitigate prejudice and lead to a very desirable increase in direct voluntary admissions to those hospitals The detailed tables now published (Tables 13, 14, 15, 16, and 23) make the importance of the matter clear

A valuable addition to the report is the classification according to diagnosis and the tabulated survey of "causes and associated factors of mental disorder" among the direct admissions during the year The scheme adopted is the official one required by the Board of Control This is unfortunate since the diagnostic schedule is in some respects obsolete the revised classification of the Royal Medico Psychological Association (1932) would be much more useful, and would permit comparison with the statistics of other countries The ætiological table is informative Naturally it reflects prevailing theories, sexual excess, for example, is now passed over as a cause of insanity, and heredity is held to be much less often responsible than critical periods of life or prolonged mental stress in a third of the admissions the psychiatrist could not discern any principal cause of the disorder

The provision of vocational training for patients living in the community is not now restricted, as formerly, to defectives, a prophylactic experiment has been begun, aiming at the rehabilitation of patients recovering from a mental illness to which their maladjustment in industry had contributed The occupations of the defectives on leave of absence from institutions, or under statutory control, is again shown to spread over a wide field, with factory work as the commonest choice, it is pleasant to see that the "midget in midget troupe" is still holding her audiences, though the "artist" and the "pasteuriser (wine)" who figured in the previous year's report have now faded from view The scientific investigation of deficiency has not been neglected in the Council's hospitals, as may be seen in the survey at the end of the report On research throughout the mental hospitals the report gives interesting data, and also on the work of the Maudsley Hospital, with its out patient ramifications, and on the financial aspect of the mental health service

MEDICAL PRIVILEGE

SIR ERNEST GRAHAM-LITTLE, M P, was denied the second reading of his Medical Practitioners' Communications Bill last week, the House of Commons negativing it without a division It proposed to establish that any information obtained by the practitioner in the course of treating a patient should be regarded as confidential and should be privileged from disclosure in a court of law There are several hackneyed methods of damning a private member's Bill The first, of course, is to censure the drafting—a line which can usually be safely taken against Government Bills as well. The second is to abuse the Bill for not going far enough, the third to abuse it for going too far The third method was the most popular last Friday All the critics of the Bill declared that they would have been quite sympathetic towards it if only its scope had been restricted to non-disclosure in cases of venereal disease A

[3] Annual Report of the L C C 1935 Vol VI Mental Hospitals and Mental Deficiency No 3234 London P S King and Son Ltd

Bill with this limited objective was as it happens introduced by Sir E Graham Little in 1927 Had it then been welcomed with the enthusiasm which Members of Parliament now show for its proposals retrospectively perhaps it might have been passed into law Its fault possibly was that it did not go far enough But it is disappointing to find that the legislative genius of Westminster cannot hammer a Bill however clumsy the original shape into serviceable form The Solicitor General was singularly pessimistic last week Sir E Graham Little's Bill was hopeless nothing could be done to improve it it must die

Meanwhile the medical practitioner is left in doubt and difficulty Last summer a doctor was judicially scolded for disclosing the disease for which a patient had consulted him It was a civil case at Leeds assizes The patient was dead His widow was suing the doctor to recover a sum of money said to have been lent by her late husband Mr Justice CHARLES was horrified at the breach of privilege What do you mean he demanded by revealing what ought to be a matter of the most sacred confidence between you and your patient? Usually the judicial bombardment thunders from the other flank How dare a doctor claim privilege for professional secrets when summoned to give evidence in a court of law? The dilemma as Sir E Graham Little reminded the House of Commons last week has been particularly unfortunate in the treatment of venereal disease The Royal Commission of 1916 was satisfied that this racial scourge could be reduced within narrow limits by early and efficient treatment it recommended free clinical facilities for the whole community and it insisted upon the importance of secrecy if patients were to show the necessary trust in consultation and treatment under the scheme Official regulations made under statutory authority and having the force of law were subsequently issued They enacted that all information obtained in regard to patients treated under the scheme must be treated as confidential, it being essential that patients should be fully assured of the secrecy of the arrangements That was clear enough The medical practitioner who has his own immemorial code of professional reticence in these matters understood that it was a legal as well as a moral duty In two High Court cases, however the doctor was subsequently told that the secrecy enjoined by the Venereal Disease Regulations did not mean what he innocently supposed in fact if he persisted in obeying the regulations he might find himself in peril It was after the second of these cases that Sir E Graham Little introduced his original Bill in 1927

The Ministry of Health might have been conscious of some responsibility for the deadlock due to its regulations but it made no sign. If the claims of justice had to be weighed against the claims of public health the Ministry refrained from intervention. Early in 1928 the learned judge who is now Lord ATKIN in some extra judicial comment on the 1927 Bill said he thought that in some cases notably those connected with venereal disease the claims of public health far outweighed the claims of justice If this be true some Parliamentary re statement of the law is long overdue If disclosure is never insisted upon where the fiduciary relationship of solicitors and their clients is concerned why must it always be insisted upon in the case of doctors and their patients? Would Parliament accept as an initial step a measure to recognise medical privilege in civil but not in criminal proceedings? The result would not be what doctors and patients understand by professional secrecy but it might meet some of the criticism which complains that medical privilege may shelter murderers and abortionists If no such compromise be acceptable we hope that Sir E Graham Little will bring in his original Bill again. If the sympathy expressed last week be genuine the third time he may be lucky

PEMPHIGUS NEONATORUM

IT has long been known that pemphigus neonatorum and pemphigus vulgaris have nothing in common but the vesicles or bullæ and the fact that either may be fatal. The former—which ought to receive some different name such as bullous impetigo of the new born[1]—is a highly contagious disease of infants that from time to time causes outbreaks in maternity or nursing homes, and is always (so far as we know) due to the *Staphylococcus pyogenes aureus* whereas true pemphigus is almost unknown in infancy is sporadic in incidence and of unknown ætiology In this country most outbreaks of pemphigus neonatorum run a relatively benign course but every now and again there are fatalities that no skill or foresight seem able to prevent. Poole and Whittle[1] found reason to think that particular forms of treatment do not affect the issue one way or the other and the list of therapeutic measures given by Normark[2] is suspiciously long including the permanganate bath (probably still the best both in treatment and prophylaxis) various mild dusting powders and weak solutions of silver salts dyes such as flavine brilliant green and methyl violet and sulphur precipitate or even mercury in ointment or calamine lotion. It is quite true as Normark says that despite any of these applications a denuded surface may extend centrifugally and when this happens the outlook becomes black. It is of paramount importance therefore when such a tendency is observed to limit and confine the spread of the infection to its primary locality and this he claims can usually be done by occlusion with Elastoplast whose use has already been advocated by Newman[3] in a very similar disease—impetigo contagiosa Adopting a procedure like Newman's and occluding the newly infected area or areas for a week at a time there were no undesirable sequel and the period of treatment is said to have been reduced from 16 days to 9 The number of cases (11 with 12 controls) was admittedly small but further trial would certainly be justified.

THE Hunterian oration of the Hunterian Society is to be given by Lord Horder at the Mansion House London on Feb 22nd at 9 P M His subject is the Hunterian tradition

ANNOTATIONS

A DISPOSITION TO CANCER

In a very interesting paper entitled Cancer and the Expectation of Life, which he read last week to the Assurance Medical Society, Dr W Cramer, of the Imperial Cancer Research Fund, pointed out that to the experimental pathologist the fundamental problem is why does this or that person develop cancer. From the point of view of life assurance the approach is quite different, for here the main question is how far does cancer affect the average duration of life, and what factors ought to be considered in assessing the risk of death from cancer in an individual applicant for insurance. The answer must clearly depend upon statistical analyses of the available data. There are three main issues, he suggested, for consideration—namely, the increase in the recorded mortality rate, the possibility of hereditary factors being present, and the possibility of causative extraneous factors other than the recognised but at present numerically insignificant carcinogenic agents discovered in a few occupations. Each of these three issues Dr Cramer discussed in turn. The first, in company with most other students of the statistics, he dismissed as unimportant. The considerable increase in the crude cancer death rate is largely due to the increasing age of the population of the country, while the rise at later ages is likely to be due to a greater accuracy in diagnosis and in the certification of cause of death. On the second, inheritance, he began by concluding that the incidence of cancer is governed by two factors, the presence of carcinogenic stimuli and the susceptibility of the terrain on which these stimuli act. Certain tissues and organs—the skin, the uterine cervix, the buccal cavity, the œsophagus, and the stomach—he regards as particularly exposed to possible carcinogenic injuries coming from without, and therefore in this group one would expect the incidence to be determined mainly by the extrinsic factor of the stimulus and less by the intrinsic factor of susceptibility. The mamma, the body of the uterus, the lower digestive tract, and the glandular tissues, on the other hand, are less exposed to stimuli from outside, and in these susceptibility is likely to predominate. After some reference to the evidence of heritable factors in mice, Dr Cramer quoted in support of these general propositions with regard to man the evidence collected by Waaler[1] in Norway and by Wassink[2] in Holland, and summed up by saying that there is conclusive evidence of a familial incidence of cancer, which is most distinct in such an organ as the mamma and least in such an organ as the lip. This leads, he said, to the "uncomfortable suspicion" that the increase in breast cancer in this country may be due to an increase in the number of people with an inherited susceptibility. To this, however, it might be answered that we have no clear evidence of such a change in susceptibility, whereas we have definite evidence of a change in a possible external stimulus, for we know that the birth rate is falling and that breast feeding is less practised than of old. The fact that the mortality rate of single women from cancer of the breast is consistently higher than that of married women also suggests the importance of an extrinsic factor. Such a difference does not, of course, invalidate the evidence for inheritance, but it does make it doubtful whether it can be regarded as of paramount importance. If it were, why should civil state affect its incidence?

Turning to extraneous factors Dr Cramer quoted the social differences revealed by Stevenson in his analysis of the national statistics of 1921–23 and some figures from Bavaria. Despite the interest and importance of the subject he can find no other European countries in which such statistical investigation has been made. The importance of the relationship lies in the fact that "it establishes for certain sites an ætiological connexion between the social status and the remote causes of cancer exactly comparable to that of occupational cancer." The explanation of the rising rates of mortality from cancer of the exposed sites as one passes down the social scale must be sought for in the habits and conditions of life of the lower social classes. The attack upon the problem must come, Dr Cramer suggested, from the collaboration of the experimental cancer researcher, the statistician, and the clinician. His own work should do much to encourage each of the triumvirate.

LIPSTICK CHEILITIS

La cheilite du rouge, as it is termed in France, was first recognised as a specific entity by R Sabouraud (Dermatologie Topographique) in 1905, but aroused little interest until after the war when the use of lipstick became more general. To day it is almost universal, and cases of intolerance to (1) the dye or pigment, (2) the perfume, and (3) the excipient or ointment base, are bound to occur from time to time. The laws of sensitisation apply here with added force, for the applications once begun are likely to be renewed, as can be commonly observed, throughout the day and part of the night, year in and year out. It follows, according to Bloch's researches, that if an irritant is contained in the cosmetic, "acquired" sensitivity is bound to develop sooner or later. The eczematous manifestations which include itching and burning, varying degrees of œdema, and even vesiculation in severe cases, need not be limited to the labial mucous membrane, but may involve the tip of the tongue and the labial commissures, and may spread thence to the chin and submental region in the form of erythematous or scaly or vesicular patches, according to the individual susceptibility. These symptoms may develop after the first or second application, or they may not occur for years, and in that event usually fail to arouse the patient's suspicions. A Sézary and A Horowitz have collected 11 proven cases of lipstick cheilitis in their practice.[1]

After considering the differential diagnosis from streptococcal and other forms of cheilitis (e g, from the use of toothpastes) the authors set out the constituents utilised in the manufacture of modern lip rouge. The commonest appears to be eosin, which yields a greenish fluorescence in aqueous solution. Rhodamine tolu safranine, and carmine are among the other pigments recovered on chemical analysis in the series examined. It is clearly important to determine if possible to which constituent—dye, perfume, or base—the cheilitis in any given case is due, as the patient when cured of her symptoms is certain to demand an innocuous formula for future use. Cutaneous patch testing will mostly serve to incriminate the constituent, this method of testing, here described in detail will certainly be found useful in practice. Full notes are included on the treatment which must be adapted to the type and stage of the reaction.

ARTIFICIAL PNEUMOTHORAX ON STATISTICAL TRIAL

THE February number of *Tubercle* contains as a supplement a report by the Joint Tuberculosis Council on the results of artificial pneumothorax treatment In the preparation of this report 200 institutions were circularised and 42 eventually collaborated No fewer than 3021 cases of pulmonary tuberculosis treated by pneumothorax have been followed to the end of 1932 The difficulty has been to provide adequate controls The first control group comprised 1320 cases from the same institutions in which pneumothorax either had failed altogether or had been abandoned within three months. But it is arguable to say the least that this A.P failed group is likely to show poor results for even if the presence of pleural adhesions does not aggravate the prognosis psychological reasons for discontinuing the treatment will almost certainly do so Foreseeing this objection the committee appointed by the Joint Tuberculosis Council decided to be as self critical as possible, and with actuarial assistance from Mr G D Stockman proceeded to compare their pneumothorax results with those obtained in 2750 cases treated at Midhurst Sanatorium between 1911 and 1929 only about 1 per cent of which had pneumothorax treatment Unfortunately these cases had been classified on a different system and there were two other factors that made the prognosis in the Midhurst cases better than that of most other institutions—first that the middle-class patients from whom this sanatorium is supplied have better facilities for after care than the mainly working-class patients on whom the present inquiry is based and secondly that they had already undergone selection the sanatorium having been endowed for the treatment of early and curable cases Had the artificial pneumothorax cases shown a definite advantage, group by group over the Midhurst figures a clear statistical case would have been made out for this form of therapy ; but as it is Mr Stockman finds that the results are inconclusive

Few if any clinicians with much experience of pneumothorax treatment doubt its value in suitable cases, and it is impossible to avoid a feeling of disappointment that four years painstaking and comprehensive work should have failed to establish a statistical basis for this conviction

THE NERVOUS HEART

MORE attention is at last being paid to the very common symptoms misinterpreted by patients—and occasionally by their doctors—as due to heart disease In our own columns Dr Doris Baker[1] has examined them from the cardiological standpoint and in a paper by Yaskin[2] we now have the observations of a psychiatrist His two main conclusions are first that cardiac manifestations are found in all forms of neurosis being often the predominant symptom and secondly—which is more questionable—that true cardiovascular disease is very often associated with neuropsychiatric disorders His first conclusion he points out is not surprising when it is recalled that anxiety is the central symptom of nearly all neuroses and psychoneuroses and that the heart has a rich sympathetic and parasympathetic innervation that causes it to respond to states of fear Moreover the secretion of adrenaline under emotional stress will also affect the heart by accelerating its beat Investigating 100 cases Yaskin found that palpitation was the outstanding symptom in anxiety neurosis and usually yielded to treatment. In conversion hysteria cardiac complaints were uncommon they mostly consisted in vague precordial pains and a statement by the patient, who showed no anxiety that he had heart disease or heart weakness In anxiety hysteria on the other hand cardiac complaints were fairly constant and severe, mainly taking the form of attacks of tachycardia and precordial discomfort ; indeed three of Yaskin's patients had actually had subtotal thyroidectomy with no relief of symptoms Here the most important therapeutic agent was held to be partial analysis but sedative and tonic medication played a considerable part In patients with compulsive-obsessive reactions palpitation and a feeling of impending death were the symptoms aroused by the patient's attempts to disobey his thoughts or impulses ; and in these cases again no treatment was of real value except partial analysis The 3 patients regarded as having true neurasthenia gave palpitation precordial discomfort, and heart consciousness as their main symptoms

THE FEEDING OF THE NATION'S CHILDREN

THE New Fabian Research Bureau has issued a booklet[1] setting out in some detail a scheme for improving nutrition in this country The author Mrs Barbara Drake first cites various reports and opinions about the prevalence of malnutrition and then draws attention to the fact revealed in nearly every survey of diets that large families come off worst. Sir John Orr has estimated she reminds us that 20–25 per cent. of the children of this country are among the poorest 10 per cent of the population and receive diets that are deficient in all respects After explaining the working of the present statutory arrangements for supplementing the diets of mothers and children she points out the advantages of collective feeding and builds up her plan. The present provisions she says, are inadequate because they do not go far enough and are only used patchily for instance in some districts cheap and free milk is allowed only to those pre school children who are under a year old, in others it is given to those up to five in others again it is not given at all. The selection of school-children for free meals is sometimes made on the recommendation of the school doctor and sometimes on an income basis and at present there is some lack of agreement between the Board of Education and the Association of Local Education Committees on the need to wait for evidence of malnutrition before free meals can be ordered. The arrangements under the Milk Act are considered inadequate for the reason that thousands of children belonging to large families cannot afford to pay even 2½d a week

The advantages of mass method of catering are obvious they permit of expert planning and buying cheaper meals and regular markets and remove the responsibility from the unskilled housewife In view of these facts Mrs Drake recommends that the organisation of an adequate milk supply for mothers and infants should be made compulsory for public health authorities ; that the milk in schools scheme should similarly be made compulsory and extended to all types of grant aided schools, and that in these schools, too, the education authorities should have to establish canteens and to provide a hot midday meal. It is suggested that the cost of these schemes should be taken on in three stages: in the first stage the cost would be limited in extent and some charge be made to the families, in the second there would be lower charges and wider application, and in the third the parents' payments would be abolished. The cost of the three stages is estimated, respectively, at some 23, 44, and 65 million pounds and would be met by the Exchequer and local authorities. These plans are one way of meeting a need which undoubtedly exists even if its extent has not been gauged. They are put forward with practical knowledge of the problem, and they would safeguard the nourishment of the coming generations in a more effective way than grants in money or in kind could ever do. Moreover, they are designed to help adult nutrition by relieving parents of some expenses. One cannot help wishing however that the argument had not made use of two questionable implications. The first is that the occurrence of some physical or mental defect or impairment of health in 27 per cent of 3000 "unselected" children was attributable to malnutrition. The second is that the expenditure of 60 million pounds would be neutralised by saving on the expenses of sickness. It will be seen from our Parliamentary Intelligence that some of Mrs Drake's arguments were used in the House of Commons on Feb 3rd but failed to produce a majority in favour of a change in policy. One cannot help noticing, however, that in each successive debate the Government defend themselves by explaining that the provision of milk and meals has now in fact been increased.

[1] Nutrition : a Policy of National Health By Barbara Drake L.C.C. with an Introduction by Eleanor Rathbone M.P. Pamphlet No. 31 of the New Fabian Research Bureau 37, Great James-street London W.C.1. Published by the N.F.R.B. by Victor Gollancz Ltd London 1937 Pp 36 6d

Some of us, who do not question the need to see that children are better fed, may perhaps be allowed to wonder whether the collective feeding of most of our children for the main meal of the day throughout the whole year will kill the kitchen sense still remaining. Will not communal feeding, for better or for worse, be required for those children when they grow up? Is the time come to despair of educational methods and of the adjustment of purchasing power?

THE WORLD CONSUMPTION OF NARCOTIC DRUGS

In a Statement of 61 pages issued by the Supervisory Body under the Convention of 1931 for limiting the manufacture of dangerous drugs, information additional to that reported in our issue of Jan 9th is furnished. From this it appears that since 1934 the amount required for world consumption, as such, of heroin has much declined, that for cocaine and codeine has shown some reduction, while that for morphine has during the last three years increased. Under the Convention each Government is required to furnish with its estimates a "statement explaining the method by which the several amounts included in the estimates have been arrived at." Nevertheless every year many estimates are received in which the description of the methods adopted is lacking; this occasions difficulty and delay and reference back for further information. In an annexe to the statement there is set out a comparative table showing for certain countries the estimated consumption of morphine, heroin, codeine, and dionin per million inhabitants for the years 1934 to 1937. In the case of morphine in 1937 Poland stands lowest with 1·5 kg, Denmark highest in Europe with 29·6 kg, while Great Britain is credited with 16·1 kg. For the United States the figure is given as 17·5 kg and for Canada 11·7 kg, while that for Japan is 21·9 kg. Somewhat similar remarkable variations in consumption are recorded in the case of the other alkaloids.

FITNESS

Most general practitioners recognise the wisdom of allowing a patient to prescribe within limits his own treatment. The Government, acting as physician to a none too healthy nation, has followed this same course in its proposals for the promotion of physical training and recreation. From the patient's point of view the assurance that there is to be no nasty medicine in the form of compulsory drill will allay some apprehension. The reasons for avoiding compulsion, given in the White Paper[1] setting out the Government's proposals, are first that any such thing would be against the national character and also that—

> "The aim of the Government is not to secure that between certain ages every boy and girl practises a certain physical exercise or achieves a certain standard of physical development, but to inculcate a wider realisation that physical fitness has a vital part to play in promoting *a healthy mind and human happiness. It is a way of* life and an attitude of mind the importance of which *is continuous and not limited to certain years in early youth.*"

The proposals are that funds and two central advisory councils (one for England and Wales, the other for Scotland) should back up and extend the organisations existing at present and that a National College of Physical Training should be established by the Government. The job of the advisory councils will be to advise on what is needed and how it can best be achieved. They will also have to promote the establishment of local committees and suggest means of publicity and propaganda. They will each consist of about thirty men and women. In addition the Government propose to appoint two grants committees, each consisting of three people, to consider applications for grants, and make grants if approved by the responsible minister, the President of the Board of Education or the Secretary of State for Scotland. The local committees will have the responsible jobs of making public interest active and of expressing views on the relative importance of the various proposals; they will have to say to what extent the cost of any scheme could be met from local sources and they will be the bodies to confront with suggestions. They will each have a paid secretary.

The primary purpose of the National College of Physical Training will be to fill in the gaps that are at present most conspicuous. First and foremost it is to train leaders to organise and undertake recreational physical training. It will also be used to help supply elementary school teachers trained in the use of apparatus, and teachers for boys' secondary schools where needed, although the training of school teachers is not ranked among the main purposes. The College will also provide the opportunity for research into the physiology of physical *training.* Women are not excluded from the College but it is recognised that for them in England, and for both sexes in Scotland, suitable colleges are already in being.

About £2,000,000 will probably be needed for the first three years of the programme and about £150,000 a year after that. It is to be spent partly of course on the new college and on new gymnasiums, playing fields, swimming baths and other means of healthy physical recreation. It will not be handed over to central voluntary organisations for distribution, but grants will be given to them mostly for some express project or to help them to assist local voluntary bodies. In particular grants are to be made to the Central Council of Recreative Physical Training so that it may give expert advice on forms of physical recreation and provide for the training of teachers and leaders while the new college is being established. This central council which is composed itself of all national organisations (over 100 in all) concerned in any form of physical recreation, only came into being about eighteen months ago. Already its activities are widespread and, judging by its third News Leaflet, it is engaged in encouraging just those activities that the Government wish to stimulate. It can be no mere coincidence that the Council was formed so opportunely, for it is proving an essential link between the Government organisation and the host of voluntary and other bodies with whom the Government plans to coöperate. Boxing, camping, cycling, dancing, games, athletics and swimming are all within its province, offering assurance that the Government plans to interpret physical recreation in a wide sense. Even these enjoyable employments cannot replace the delights of leisure in the country; moreover, as the *Manchester Guardian* puts it, lack of sun, bad atmosphere, small and insanitary houses, and above all too little of the right food and not enough of any, will no more be cured by exercise than lunacy was cured by a strait-jacket. But regarding the Government's proposals as a palliative rather than a panacea we must nevertheless accept them gratefully.

LONDON VOLUNTARY HOSPITALS: A STATISTICAL REVIEW[1]

In 1921 the London voluntary hospitals had a complement of 13 300 beds; in 1935 they had 18 020 which were, moreover, used to greater advantage, for not only has the average number of *occupied* beds risen during the same period from 11 070 to 15 110 but the average stay of each in-patient has been shortened by three days. The number of new in-patients admitted was 172,200 in 1921 and 274 100 in 1935. Less satisfactory from some points of view is the increase of the annual number of out-patients from 1 545 000 to 1 872 000 and of out-patient attendances from 6 661 000 to 9 777 000. These figures, showing over three million more attendances in 1935 than in 1921, demand careful consideration in view of the suspicion, often expressed but difficult to prove, that the hospitals are here encroaching upon the domain of private practice. An ingenious if not entirely reassuring explanation of the increased attendances is offered by King Edward's Hospital Fund in this statistical survey, when it is pointed out that the average number of attendances per out-patient was 4 3 in 1921, 5 in 1930 and 5 2 in 1935. The suggestion is that the large number of attendances is associated with the modern conception of the proper function of an out-patient department—i.e., its development on consultative lines and the provision of facilities for specialised long-term treatments; while patients with trivial complaints, that do not require hospital treatment or for which other more suitable agencies are available, are discouraged. Support is found for this theory in the fact that the annual number of *new* out-patients, which increased by 342 000 during the period under review, is now approaching a fairly constant figure, the increase having been only 67 000 in the last five years of the period.

On the financial side the total receipts, including donations of capital and endowments, have risen from £3 440 000 to £5 100 000. It is of interest that in 1921 the percentage of the total receipts made up of voluntary gifts was 59 0 and in 1935 only 53 9, while the percentage of receipts for services rendered was respectively 25 8 and 33 2. Under this last heading are included receipts from contributory schemes, notably the Hospital Saving Association, from local authorities and from patients direct, including pay-bed patients. The rest of the total receipts are derived from investments, in proportion (13 to 14 per cent.) of the total not materially changed since 1921.

The annual *maintenance* income has risen from £2 751 000 in 1921 to what is described as the "imposing figure" of nearly £4,200 000 in 1935. This income has been sufficient to provide an aggregate credit balance in all but 2 of the 15 years for ordinary running expenses, though special help from the public is needed and will continue to be needed for any rebuilding, extension, or major improvements. Attention is drawn to the astonishing growth of voluntary payments by patients; this is a most encouraging feature in so far as it reflects public confidence in the voluntary hospitals and is not allowed to destroy their charitable purpose. We have known instances of refusal to attend, or to return to, a hospital by those ashamed to admit inability to contribute to the cost of their maintenance and treatment. This deplorable outcome of a too business-like reception is fortunately rare when the services of judiciously trained almoners are available, and it is satisfactory to know that more and more hospitals are employing them.

The Royal College of Surgeons of England is holding its Hunterian festival dinner next Monday evening. In the afternoon at 4 o'clock Prof. G. E. Gask will give a special lecture entitled John Hunter in the Campaign in Portugal (1762–63).

Sir Thomas Dunhill has chosen the surgery of the thyroid gland as the subject for the Lettsomian lectures which he is giving to the Medical Society of London on Feb. 15th, 24th, and March 1st. He will speak at the house of the Society, 11, Chandos-street, W., at 9 P.M.

On Thursday, Feb. 18th, and the following Tuesday Dr. P. M. D'Arcy Hart will deliver the Milroy lectures to the Royal College of Physicians of London at 5 P.M. He will speak on measures for the prevention of pulmonary tuberculosis among adults in England—in the past and in the future. Members of the medical profession will be admitted on presentation of their cards.

INDEX TO THE LANCET, VOL. II, 1936

The Index and Title-page to Vol. II, 1936, which was completed with the issue of Dec. 26th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of The Lancet, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

PRINCIPLES OF MEDICAL STATISTICS

VII —FURTHER PROBLEMS OF SAMPLING DIFFERENCES

In the previous section the calculation of the standard error of a proportion was based upon a knowledge of the proportion to be expected from some past experience—e g , if past experience shows that on the average 20 per cent of patients die, how great a discrepancy from that 20 per cent may be expected to occur by chance in samples of a given size In practical statistical work the occasions upon which such past experience is available as a safe and sufficient guide are relatively rare As a substitute for past experience the experimenter takes a control group and uses it as the standard of comparison against the experimental group For instance, as the result of the collection of data in this way, we may have the following figures —

50 patients with pneumonia treated by the ordinary orthodox methods had a fatality-rate of 20 per cent ,

50 patients with pneumonia treated by the ordinary orthodox methods *plus* special method X had a fatality-rate of 10 per cent

Is this difference more than is likely to arise merely by chance? It is clear that *both* these percentages will, by the play of chance, vary from sample to sample , if method X were quite useless we should, if the results of a large number of trials were available, sometimes observe lower fatality rates in groups of patients given that treatment, sometimes lower fatality rates in the control groups, and sometimes no differences at all In the long run—i.e , with very large samples—we should observe no material difference between the fatality rates of the two sets of patients , if method X is useless (but innocuous) the difference we expect to observe is, clearly, 0 Our problem is to determine how much variability will occur round that value of 0 in samples of given sizes, how large a difference between the two groups is likely to occur by chance In other words we need *the standard error of a difference between proportions*

DIFFERENCES BETWEEN PROPORTIONS

To return to the example previously adopted, let us suppose we take samples from a universe in which is recorded the number of colds suffered by each individual, and for each sample we calculate the proportion of persons who have no colds at all In the universe itself the proportion of persons having no colds is, we will suppose 10 per cent If we take two random samples from the universe, each containing 5 persons, we shall not necessarily observe a proportion of 10 per cent with no colds in each of these samples , in one sample we may obtain a percentage of, say, 20 and in the other a value of, say, 60, giving a difference of 40 per cent Is that a difference that is likely to occur by chance in taking two samples of 5 individuals from the same universe? As a test 100 *pairs* of samples of this size were taken from this universe After each pair had been taken the proportion of the 5 persons in each who had had no colds was calculated and the difference between these two proportions noted—e g , in the first sample 1 of the 5 individuals had no colds in the second sample 2 of the 5 individuals had no colds the percentages were therefore, 20 and 40 and the difference between the percentages was 20 This procedure gave the following distribution of *differences between the pairs*

—	Proportion of persons having no colds in two samples of 5 persons	
	Differences between percentages in the two samples	No of pairs of samples with given difference.
Smaller % in sample A than in sample B	−60	1
	−40	2
	−20	26
	0	45
Larger % in sample A than in sample B	+20	22
	+40	4
	+60	—
—	—	100

In nearly half the pairs of samples (45 instances) there was no difference between the percentages having no colds , but there was a considerable scatter round that difference of 0 that we expected to see For instance in 6 instances the percentage difference was 40 and in 1 it was as much as 60 The mean of the 100 percentage differences is very nearly 0, being −0 6, but very frequently a difference of 20 per cent was observed between one pair of samples The scatter of the differences round that mean may be measured, as usual, by the standard deviation , it is 18 0 The distribution of the differences round the mean is, it will be observed, fairly symmetrical, and in a distribution of that shape we know that values that differ from the mean by as much as plus or minus twice the standard deviation are of relatively frequent occurrence We may therefore say that in samples of this size, in which a percentage of 10 is expected in each, and therefore a difference of 0 between two samples, we may in fact easily observe by chance not that difference of 0 but one as large as ±2 (18)=36 per cent between the proportions in two samples, differences larger than that will be relatively rare.

Increasing the size of each sample to 20 showed a different distribution of differences between the pairs The largest difference between 2 samples is now only 25 per cent (larger differences would be observed if the numbers of samples taken were increased, but these large differences are so infrequent that they are unlikely to occur with only 100 pairs)

—	Proportion of persons having no colds in two samples of 20 persons.	
	Differences between percentages in the two samples	No of pairs of samples with given difference
Smaller % in sample A than in sample B	−25	—
	−20	6
	−15	6
	−10	15
	− 5	14
	0	27
Larger % in sample A than in sample B	+ 5	14
	+10	12
	+15	3
	+20	2
	+25	1
—	—	100

The mean of the difference between the 100 pairs is again nearly 0—namely, −1 3 per cent —but the scatter round that mean as measured by the standard deviation now becomes 9 5 , multiplying the size of the sample by 4 has reduced the variability of the differences by half In samples of size 20, in which a percentage of 10 is expected in each, and therefore a difference of 0 between two samples, we conclude that differences of ±2 (9·5) = 19 per cent between two samples may in fact easily occur by chance while greater differences will be relatively rare.

Finally taking pairs of samples of size 50 gave the *following distribution of differences in percentages* having no colds.

—	Proportion of persons having no colds in two samples of 50 persons.	
	Differences between percentages in the two samples	No of pairs of samples with given difference.
Smaller % in sample A than in sample B	−14	1
	−12	—
	−10	4
	− 8	6
	− 6	7
	− 4	2
	− 2	19
	0	6
Larger % in sample A than in sample B	+ 2	17
	+ 4	17
	+ 6	10
	+ 8	2
	+10	3
	+12	5
	+14	1
—	—	100

In the 100 pairs no difference between the proportions now exceeds 14 per cent. The mean of the 100 differences is +0·9 and the scatter round that mean as measured by the standard deviation is 5·7. In samples of size 50 in which a percentage of 10 is expected in each and therefore a difference of 0 between two samples differences of ±2 (5·7) = 11·4 per cent. will in fact be relatively frequent and greater differences relatively rare. The standard deviation or standard error of the differences decreases it will be seen with increasing size of sample.

STANDARD ERROR OF THE DIFFERENCE

The standard error of each proportion is, as shown in the previous section, $\sqrt{\frac{p \times q}{n}}$ where p is the percentage in the universe in one category—e.g. having no colds—and q is the percentage in the other category—e.g. having one or more colds—and n is the number of individuals in the sample. *The standard error of the difference between the two proportions* is it may be shown $\sqrt{\frac{p \times q}{n_1} + \frac{p \times q}{n_2}}$ where n_1 and n_2 are the numbers in the two samples. For instance in samples containing 5 individuals drawn from a universe in which $p = 10$ per cent and q therefore $= 90$ per cent the standard error of the difference between the proportion in sample A and the proportion in sample B is $\sqrt{\frac{10 \times 90}{5} + \frac{10 \times 90}{5}}$ = 19·0 per cent. In other words in a single pair of samples each containing 5 persons drawn from the same universe we may instead of obtaining the expected percentage difference of 0 quite easily get a difference of ± 2 (19) = 38 per cent. This theoretical value it will be observed agrees closely with the value that was obtained practically from the test; the differences found with the 100 pairs of samples of size 5 had a standard deviation of 18. Similarly the standard deviation of the differences between samples of size 20 was found in the test to be 9·5. The theoretical value is $\sqrt{\frac{10 \times 90}{20} + \frac{10 \times 90}{20}} = 9·5$. *Finally* the standard deviation of the differences between samples of size 50 was 5·7 and the theoretical value is $\sqrt{\frac{10 \times 90}{50} + \frac{10 \times 90}{50}} = 6·0$.

Clearly if we knew the proportion of individuals having no colds in the universe that we were sampling we could calculate the size of differences between two samples that might reasonably be expected to occur merely by chance in taking samples of a given size. If, for example from the universe used above we *took two samples of 50 persons and we treated* one sample with, say vitamin A and found in that sample the proportion of persons having no colds over a specified period of time was 4 per cent while in the sample not so treated it was over the same period of time 14 per cent. the standard error tells us that that difference is one which might easily arise by chance. The percentage difference between the two samples is 14 − 4 = 10 and this difference we have seen, has a standard error of 6 per cent. In other words in taking two samples of 50 individuals from the *same* universe we might easily obtain proportions in the two samples that differed from one another by as much as twice 6 per cent. a difference of 10 per cent is not, therefore a very unlikely event to occur merely by chance with samples of this size. The lower *percentage cannot safely be ascribed to* the effect of vitamin A for the same difference might quite often occur even if vitamin A were ineffective.

THE STANDARD ERROR IN PRACTICE

In actual practice we do not of course know the value of p in the universe in calculating the standard error we have to substitute for it a value calculated from the samples. In making this substitution two slightly different lines of reasoning are possible.

(i) We have observed two *samples of 50 persons* each and the proportion of persons with no colds is 4 per cent in one sample and 14 per cent in the other. Is it reasonable to suppose that these two samples have been drawn from one and the same universe in which the percentage of persons with no colds is "x" and that the differences of 4 and 14 from "x" are merely due to chance? Let us adopt the hypothesis that they *are* both samples of this one universe. Then the best estimate that we can make of "x" is given by the *whole* of the observations we have—i.e. *the percentage of persons having* no colds in our total 100 observations—which is 9. Our question now becomes this: If we take two samples each of 50 individuals from a universe in which the proportion of persons having no colds is 9 per cent are we likely to observe a difference of 10 per cent in the proportions observed in the two samples instead of a difference of 0? If the answer to this question is *yes* then we must recognise that though the difference observed *may* be a real one it is quite likely that it is only a chance difference which would disappear if we *repeated the experiment*. On the other hand if the answer is no we can conclude that our hypothesis that these two samples are likely to be drawn from the same universe is probably not true—i.e. these samples differ from one another by more than is likely to be due to chance and we are entitled to look for some other explanation of the difference between them.

In the example above the difference observed is 14 − 4 = 10 per cent. On the hypothesis outlined above the standard error of this difference is $\sqrt{\frac{9 \times 91}{50} + \frac{9 \times 91}{50}}$ = 5·7. The observed difference between the samples is less than twice its standard error and we conclude that its occurrence merely by chance is not a very unlikely event—that relatively often we might observe a difference of this magnitude If the difference had been 15 per cent we should have concluded that one of this magnitude was unlikely to have occurred by chance, since this difference is more than twice its standard error, and that therefore some cause (perhaps treatment with vitamin A if we are satisfied that the samples were equal in all other relevant respects) had led to the samples differing

(ii) The alternative approach is to make the hypothesis that the samples are in fact drawn from two different universes, we then test whether the results given by the samples are compatible with the hypothesis that the difference that ought to have been reached in sampling those two universes is zero—i e, that the two universes are in fact identical In this case we use as p and q the values found in each sample and the standard error of the difference of 10 per cent is equal to $\sqrt{\frac{4 \times 96}{50} + \frac{14 \times 86}{50}} = 5\ 6$ As the difference is not twice its standard error we conclude that there is no good reason for supposing that the two universes sampled are different (Some workers prefer to retain the hypothesis that the samples are drawn from the same universe We do not know the proportion in that universe but can take the different sample values as two separate estimates of it and use them as above for calculating the standard errors)

It will be noted that the two methods give very nearly the same results and in practice this is usually the case

DIFFERENCE BETWEEN TWO AVERAGES

The same type of test is applicable to the difference between two averages, or mean values For example, the mean height of a group of 6194 Englishmen is 67 38 inches and the mean height of a group of 1304 Scotchmen is 68 61 inches Are Scotchmen on the average taller than Englishmen or is the difference merely due to chance, inherent in sampling ? The standard error of the mean is, it has been shown, $\sigma/\sqrt{n}$, where σ is the standard deviation of the universe sampled and n is the number of individuals in the sample For this standard deviation of the universe we have to substitute the standard deviation of the sample The standard deviation of the 6194 Englishmen measured was 2 564 inches, and the standard error of their mean is therefore $2\ 564/\sqrt{6194} = 0\ 033$ The standard deviation of the 1304 Scotchmen measured was 2 497 inches, and the standard error of their mean is therefore 0 069 The standard error of the *difference* between the two means—i e, the amount of variability the differences might show if we took repeated samples of this size—is $\sqrt{\frac{\sigma^2}{n_E} + \frac{\sigma^2}{n_S}}$, where n_E is number of Englishmen and n_S is number of Scotchmen measured Unless the observed difference is at least twice this value it might easily have arisen by chance—i e, the difference between the means ought to be 0 and differs from 0 only by chance As with proportions we have two alternatives (i) We may substitute for the standard deviation of the universe the standard deviation of *all* our observations, Englishmen and Scotchmen, put together The value of this standard deviation is 2 595 By its use we are asking ourselves the question "Is it reasonable to suppose that we could draw two samples from one and the same universe, in which the standard deviation of the individuals is 2 595, and obtain two means differing from one another by as much as the difference between 68 61 and 67 38 ?" Inserting this value of the standard deviation we have as standard error $\sqrt{\frac{(2\ 595)^2}{6194} + \frac{(2\ 595)^2}{1303}}$, $= 0\ 079$ The difference between the two means is 1 23 inches, and this is 15 6 times the standard error, it is, therefore, very unlikely that we are drawing samples from the same universe In other words, Scotchmen are on the average taller than Englishmen—presuming the samples to be representative of the nationalities

(ii) Alternatively we may use the formula $\sqrt{\frac{\sigma_E^2}{n_E} + \frac{\sigma_S^2}{n_S}}$, $\sqrt{\frac{(2\ 564)^2}{6194} + \frac{(2\ 497)^2}{1304}} = 0\ 076$ In this case the difference between the averages is 16 2 times its standard error In this test we are presuming that we have drawn the two samples from universes which differ in the variability of their individuals (or from one universe, of the variability in which we have two estimates) and we want to know whether they differ in their means The two methods give closely the same results

It must be remembered that none of these methods is applicable to very small samples Finally a moment's consideration ought to be paid to the level of significance adopted. It has been shown that values, whether of an average or a proportion, that differ from their mean by more than twice the standard deviation are relatively rare As a conventional level twice the standard error is therefore adopted, and differences between values in two samples which are greater than twice the standard error of the difference are said to be "significant" In fact, differences of this size would occur by chance nearly 5 times in 100 tests If a worker regards this test as too lenient he can raise his level of significance to $2\frac{1}{2}$ or 3 times the standard error, with these levels, differences would occur by chance, roughly, only once in 80 tests and once in 370 tests The problem is always one of probability and the worker is at liberty to adopt any level he wishes—so long as he makes his test clear For this reason it is better to say in reporting results that the observed difference is, say, 2 5 times its standard error, rather than that it is "significant" The latter term will be read as implying that the difference exceeded the conventional level of twice the standard error The worker who wishes to make the test more stringent may be reminded that he may thereby be classing as chance effects differences that are real, he who tends to be too lenient may class as real differences that are due to chance With borderline cases there is only one satisfactory solution—the accumulation of more data

Summary

In practical statistical work the problem that most frequently arises is the "significance" of a difference—e g, between two proportions, two means, or any other values The difference between two such values in a pair of samples will fluctuate from one pair of samples to another, and though the samples may be drawn from one and the same universe we shall not necessarily observe a difference of 0 between them The object of the statistical test is to determine the size of the difference that is likely to occur by chance

SPECIAL ARTICLES

THE FACTORIES BILL

BEFORE this appears Sir John Simon will have moved the second reading of the Bill to consolidate and amend the *Factory and Workshop Acts 1901–29* and the biggest public health measure of our time will be before the House of Commons We were able to indicate last week the main changes proposed in existing practice and we may well congratulate those who have thought them out with such care. The Bill contains within it so much that is valuable that those who hope to achieve social progress at one stroke should not permit their anxiety to allow them unduly to obstruct the passage of the Bill into law

Especially good are the General Safety Provisions (Part II) which are obviously the work of men who know their job But surely means of access to fire escapes (§35) should not only be marked by a printed notice but should also be kept free from obstruction (as required in §33) ?

Among the General Health Provisions (Part I) §3 aims at securing a reasonable temperature in a work place and provides the control over braziers, gas fires, and stoves, with their risk of carbon monoxide poisoning, that recent experience has shown is so necessary It is perhaps open to question whether a minimum temperature of 60° F is high enough to guard sedentary workers against the ill effects of body cooling §2 gives power to modify the proposed regulations respecting overcrowding in existing work rooms in which effective mechanical ventilation is provided This might be a dangerous exemption. Is it possible to get effective ventilation in small rooms and shops (apart from air conditioning) without creating a draught ?

We regret—and our regret will be shared both by industry and the workers—that it was not possible to incorporate in the Bill more exact definitions of reasonable and adequate or effective standards to govern environmental conditions such as lighting and ventilation. The difficulties no doubt are great but the only alternative is to give such wide powers to the inspectorate as to make their responsibility very great.

§11 gives the Secretary of State power to make regulations for medical supervision in any factory in which excessive illness has occurred or in which potential risk of illness appears to him to be present Out of these powers we may hope to see the gradual development of a Health Service for Industry Since no guiding rules are laid down time alone can show what use will or can be made of this section

Under General Welfare Provisions §§41–43 govern the provision of washing facilities and the accommodation for clothing It appears that washing facilities are only to be required where a special need for them exists by reason of the amount of dust or dirt given off in the process or the dirty or offensive nature of the materials used Suitable accommodation for clothing not worn during working hours can only be enforced in occupations of a wet, dusty dirty or offensive nature ' in which workers are accustomed to remove part of their indoor clothing We may ask whether either of these two provisions really meets the health needs of a modern community

§45 which deals with welfare regulations is no doubt purposely vague Its effect must depend upon the nature of any new regulations which may be made as a result of its provisions Is there any reason, however why arrangements for preparing heating and taking meals should not be obligatory especially where night-work or shift work is carried on for more than 14 days at a time ?

Coming on to the Special Provisions §51 is welcome bringing under stricter regulation underground rooms used as factories §54 gives the Secretary of State power to prescribe the maximum weights which may be lifted, carried or moved. Medical opinion generally considers that no person ought to carry weights heavier than one-third of his body weight for any prolonged period of time

§57 prescribes the conditions under which women and young persons may be employed in certain lead processes It is hard to understand why these regulations should not apply to all persons (including men) who have to work in an atmosphere containing *lead dust.* Experience suggests that any concentration of lead above 1 5 mg. per 10 cubic metres of air is potentially hazardous We should like to see some definite standard stated for these operations and should wish also that every person whose work exposes him to a risk of lead poisoning should undergo regular medical examination A considerable number of painters still suffer from lead poisoning They should be as much under control as the accumulator makers. The definition of a lead compound as any *soluble compound of lead* appears to us unsatisfactory The solubility in water of the oxides or sulphates of lead for example, may be low but these compounds are sufficiently soluble in body fluids to give rise to poisoning Any lead compound which is soluble *in the body fluids in vivo* should be included within the definition.

In §110 provision is made for the medical practitioner who is employed by the occupier in connexion with the medical supervision of persons employed in the factory who acts as the examining surgeon for that factory for such purposes as the Secretary of State may direct." We question the wisdom of this provision It means as it stands that subject to the authorisation of the Secretary of State the medical officer (*part time* or *whole time*) of a firm may have to act at one and the same time in a semi judicial capacity and also as an employee of the firm.

Under Employment of Women and Young Persons §68 is likely to prove controversial. To permit a 9 hour day *and* a 48 hour week (or a 54 hour week for over half of the year) for women and young persons is an inadequate restriction of hours When a five-day week is worked a 10 hour working day is to be permitted and this may mean a 12 hour period *of employment* It seems *passing* strange that no legal limit should be set to the hours which a *man* can be asked to work.

But when this Bill has been safely passed—as we hope *it* will during the present session—large sections

---

(Continued from previous page)

in samples of given magnitudes how far it may deviate by chance from 0 This involves the calculation of the standard error of the difference. In reasonably large samples this standard error of a difference may be taken to be the square root *of the* sum of the two individual standard errors of the values in the two samples

A B H

of the working population will still be outside the scope of the activities of the Home Office Inspectorate Health conditions in offices and retail shops in the distribution trades and in transport and agriculture ought next to receive the attention of the legislature If it is objected that the needed powers for the regulation of these occupations already exist in the Public Health and other Acts, the reply is that they are not being so used at the present time

OXFORD UNIVERSITY PARLIAMENTARY ELECTION

Sir Farquhar Buzzard, president this year of the British Medical Association, is standing as official Conservative candidate for the Oxford University seat, vacant by the retirement of Lord Hugh Cecil, for which the polling goes on from Feb 23rd to 27th In an influentially signed address circulated by his supporters it is pointed out that Sir Farquhar's responsibilities as regius professor will allow him adequate time for Parliamentary duties inasmuch as they do not involve the administration of a scientific department and are confined to a general superintendence of the medical status of the University

The other candidates in the election are Sir Arthur Salter and Prof F A Lindemann, F R S Sir Arthur takes his stand on the policy outlined in his book "Recovery" and in "The Next Five Years" Prof Lindemann, who occupies the chair of experimental philosophy in the University, is putting up as an independent Conservative

In his election address Sir Farquhar remarks that education and research are subjects on which a burgess of the University should be able to speak with some special knowledge and authority

> The enormous improvements, he says, which have been witnessed during the last 50 years in the general standards of living, the simultaneous decrease in poverty, crime, drunkenness and dirt, and the increased expectation of health and longevity are mainly due to better education and to the results of research in every field of knowledge
>
> Apart from my professional work, education and research have been my foremost academic interests, and during the last nine years I have enjoyed the great privilege of taking part in our University affairs as a member of the Hebdomadal Council and of the General Board of the Faculties, as a curator of the University Chest and of the Bodleian Library, in addition to holding many other positions of administrative responsibility As an ex-officio student of Christ Church and an honorary fellow of Magdalen I am well acquainted with the essential share which is taken by the Colleges in the endowment and organisation of teaching and research in the University
>
> This experience, together with that derived from membership of the governing bodies of several important public and secondary schools leads me to think that our older Universities preserve their great influence for good on the younger generation, are steadily progressive in their outlook and in their commitments on behalf of education and research, and thoroughly deserve the special representation which they enjoy in an assembly where these subjects are reviewed in public Both subjects need skilled handling and careful control Education, in particular, requires wise guidance lest its primary object, that of developing a balanced critical faculty, should be lost sight of amid the clamour for early specialisation along vocational lines

Personal knowledge of teaching and examining over many years as well as more recent acquaintance with the fundamental problems of University and school management should enable Sir Farquhar to take an effective share in debate when these matters are at issue in the House of Commons

PARIS

(FROM OUR OWN CORRESPONDENT)

A PARIS MONUMENT TO LAENNEC

LAST year the celebrations over the tomb of Laennec far from Paris brought together many leaders of the medical profession, some of whom wondered how no one had thought hitherto of erecting a monument in Paris itself This question has now become concrete in a committee charged with the duty of raising a worthy memorial The president of this committee is Prof Sergent, and among its members are Profs Carnot, Roussy, Bezançon, and many others A site for the monument has already been selected, and if the municipal parties are complacent, it will stand in the square of the Charité, at the junction of the Rue des Saints Pères and the Boulevard Saint Germain The amphitheatre in which Laennec taught at the Charité is, by the way, still in existence All who wish to commemorate the discoverer of auscultation in tangible form should send their contributions to M Doury, 4, rue de la Muette, Paris 16

A NEW FIRST AID HOSPITAL

The Fondation Marmottan was formally opened on Jan 14th. The building is in the 17th arrondissement, and its equipment is the last word in modern surgery It is intended for surgical cases of a strictly emergency character, and its accommodation for 47 in patients can be doubled if necessary The hospital is, of course, open day and night, and it epitomises the present tendency to comb out for operative treatment in the heart of the city only those cases representing emergencies The equipment of this hospital is, however, as complete and elaborate as the cases for which it is intended are essentially first-aid, urgent, and accidental.

IRELAND

(FROM OUR OWN CORRESPONDENT)

HOSPITAL DEVELOPMENT

THE Charter Day dinner of the Royal College of Surgeons in Ireland was held on Feb 6th in the hall of the college The president, Mr Adams A McConnell, said some important things about the future hospital system of the country, now under the consideration of the Minister for Local Government and Public Health. He referred to the labour of the Hospitals Commission which had "produced a masterly report of national importance" The commission had insisted on the coördination of the several types of hospital. The report had been a year in the hands of the Minister, and a year was not a long time to wait, but the members of the public and some doctors were becoming restive Nevertheless, it was better to wait even longer than to launch a scheme before its details had been fully worked out The population of Dublin has increased by about 80,000 since 1930 The Lord Mayor has more than once asked what the Dublin hospitals have done to meet the extra demand for beds As far as Mr McConnell knew 50 beds had been added to the general hospital beds since the Sweepstakes began. He had to point out that neither the medical profession nor the hospitals have power to increase the number of beds the Government alone has that power As regarded hospital development in Dublin the considered opinion of the leaders of the profession is in favour of the plan suggested by the commission —the extension of the Mater Misericordiæ, St. Vincent s and the Richmond Hospitals and the amalgamation of three or four of the smaller hospitals The profession he said, is opposed to the building of a large municipal hospital. Any deterioration of the Dublin hospitals would adversely affect the efficiency of the medical schools and lower the standard of the future profession of the country The president referred also to the recent establishment of a scheme for medical research reported in this column last week.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

GLASGOW WESTERN INFIRMARY

AT the annual meeting of the qualified contributors to the Glasgow Western Infirmary the chairman of the managers referred to improved extension schemes that are contemplated It is proposed to erect on the east side of the main drive a block for paying patients and for this purpose the constitution of the infirmary was amended so as to provide for pay beds A gift of £20 000 from the Gardiner Trustees was to be used for building the medical institute which would be under the charge of the new professor of medicine Prof J W McNee The ear nose and throat wards are also to be rebuilt. The Lord Provost stated that the corporation had no intention of taking over the voluntary hospitals, but, as the health authority for the city it was entitled to find out whether the voluntary system was providing the necessary accommodation Sir Hector J W Hetherington principal of Glasgow University pleaded for more care and attention to better equipment, with more workers in medical scientific departments by the coöperation not only of the voluntary hospital but of the municipal hospitals Sir Robert Bruce paid a tribute to Prof. Sir Robert Muir s 37 years service as pathologist to the infirmary to Prof T K. Monro who after 20 years service has retired from the regius professorship of medicine and to Colonel D J Mackintosh who has been medical superintendent of the infirmary for no less than 45 years and who has also retired

PUBLIC DISPENSARIES

The important part played by the public dispensaries in Edinburgh in the treatment of the sick poor was emphasised by Lord Provost Cumley at the annual general meeting of the Edinburgh Royal Public Dispensary The present building at Richmond street will be demolished as part of a slum clearance scheme and the corporation are contributing substantially towards the cost of building a new dispensary The value of dispensary work in the teaching of students is fully appreciated and the extensive use made of the dispensaries by the sick poor has been brought into prominence recently by the fact that in the new housing areas built under the slum-clearance scheme there is no such service available and the difficulty of providing proper medical services for the new housing areas has caused considerable concern.

NEW FEVER HOSPITAL

Arrangements have been completed for the building of a new infectious diseases hospital by Glasgow Corporation at Barrhead road. The proposed new hospital will replace the Shieldhall hospital, in which the accommodation and equipment are no longer considered adequate There will be provision for 352 patients and a third of the beds will be in individual cubicles There will be 3 two storey pavilions and 8 single storey pavilions. Full provision is being made for an operating theatre and X ray unit and for various routine and research laboratories The nursing staff will number about 180

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 30TH 1937

Notifications—The following cases of infectious disease were notified during the week Small pox 0 scarlet fever 1414; diphtheria 1241 enteric fever 53 pneumonia (primary or influenzal) 3555 puerperal fever 43 puerperal pyrexia 108 cerebrospinal fever 32; acute poliomyelitis 4; acute polioencephalitis, 3 encephalitis lethargica, 0; dysentery 41; ophthalmia neonatorum 79 No case of cholera plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb 5th was 3596 which included: Scarlet fever 871; diphtheria 959; measles 17 whooping cough 590 puerperal fever 21 mothers (plus 10 babies) encephalitis lethargica 280 poliomyelitis 2 At St. Margaret s Hospital there were 16 babies (plus 7 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns, including London there was no death from small pox, 2 (0) from enteric fever 8 (0) from measles 5 (1) from scarlet fever 27 (8) from whooping-cough 32 (5) from diphtheria 38 (18) from diarrhœa and enteritis under two years and 1155 (154) from influenza The figures in parentheses are those for London itself

Liverpool and Newport reported deaths from enteric fever Manchester had 3 deaths from whooping-cough Rotherham 2 Fatal cases of diphtheria were reported from 24 great towns Manchester 3, Leeds and Liverpool each 2

The number of stillbirths notified during the week was 257 (corresponding to a rate of 44 per 1000 total births) including 35 in London

AN appeal has been issued on behalf of the University of Oxford by Lord Halifax the chancellor and Mr A D Lindsay the vice-chancellor for help to enable certain work of the first importance to be set in hand the undertaking of which long deferred has now become a matter of necessity The sum of £250 000 is required for the endowment of the extension of the Bodleian library and a further £250 000 for other buildings Funds are also sought to maintain and equip new laboratories to knowledge; to meet the demands of the new school of medical research the ancillary sciences must be strengthened No definite total sum has been asked for but it is hoped that need and generosity will result in a very large amount Lord Nuffield has contributed the first £100 000 to the appeal. Copies of the appeal may be had from the vice-chancellor the Oxford University Appeal Old Clarendon Building Oxford where subscriptions may also be sent

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM A ROVER

II

From considerations of prestige in respect of the individual doctor it is an easy transition to pass to the prestige of the profession as a whole Many of us lament that this is not what it was and is lower than it might be If we believe that it is good for the public, and also good for us that the status of medicine should be high it behoves us to inquire where the fault lies It has been said that nations get the governments they deserve, and it might be said with equal truth that society gets the doctors it deserves But might it not also be said that medicine gets the public it deserves? For inasmuch as the doctor is, or should be, a man or woman of culture above the average in the nation, and is specially trained in both the art and the science of medicine, he (I shall assume both sexes when for convenience, I use this word) has every right to lead, to teach, and even to dictate in his particular sphere,

* * *

I believe that if he put this value upon himself and upon his services the public would not only respect him more, it would accept his guidance and his dictation with relief and with benefit As it is, the public persuades itself that it is as knowledgeable in matters concerning its health as the doctor himself, and, in many instances, only needs his services when it is out of its depth by grave illness, or when it sees that it can batten upon his known generosity in the disposal of his time and energy and even his blood

* * *

If there is one reason more than another for the lack of respect for the doctor as a leader in his proper sphere it is probably the fact that he "gives" too readily in the face of fads and cults and transient notions Instead of refusing to traffic with pseudo science and pseudo art, protesting against them and warning the public that salvation does not lie in these directions, he joins in the worship of the false gods, not only passively but too often actively Oft times he fears that not to do so will proclaim him "narrow minded." Whereas it is just this sort of narrow mindedness that constitutes one of the doctor's chief duties to the public After all, it is only he who can detect the cloven hoof and, when he sees it, it is in the public interest that he shouts the fact from the house tops

* * *

If we look down the lists of patrons and committees of many of the health "movements" that originate in the vanity and half knowledge of retired service men, priests, financiers, and litterateurs we find the names of medical men in abundance The public does not know, as we do, that the same names recur in a number of these lists and that the names have no meaning for us except that they belong to colleagues of whom we are heartily ashamed, men with anti minds, who have an itch for the irregular and the unorthodox Charity leads us to say that they "believe" in the queer doctrines they support, but, even if they do, it is our duty to proclaim them as anti social. Examples would fill my "Grains and Scruples" pages, but here is one, to hand this week. "The Health Education and Research Council" has, as one of its professed objects, "the encouragement and support of methods of healing which are dissociated from experiments on animals such as Homœopathy, Herbalism, Nature Cure, Osteopathy wireless wave therapy, vegetarian and fruitarian systems of dietetics " Some thirty legally qualified British doctors are listed as "advisory members" and their names are printed at the head of the circular letter Accompanying the letter is a book with the title "Cancer the failure of modern research" The 'blurbs" printed on the paper cover are extracts from two reviews which appeared in a couple of medical journals One of these states that "the book throws a flood of light on the absolute failure of modern cancer research" The other says, "this is an excellent exposure of the failure of modern cancer research which we have long recognised to be conducted on entirely wrong lines" Unfortunately we are not told what are the right lines along which cancer research should be conducted.

* * *

In parentheses under the main heading of this circular letter occur the words "International. Dissociated from Experiments on Animals" Which seems to suggest that these are our old friends the Anti Vivisectionists in a new guise And, on reflection, we are confirmed in this view by some of the names on the executive committee I wonder if it has occurred to any of the doctors on the advisory board that if they neglected to use antitoxin in a case of diphtheria nowadays they would almost certainly incur a charge of criminal neglect? But since martyrdom has its own special attraction for some folk this consideration, after all, may not have been lost sight of

* * *

The influenza epidemic has given a great fillip to the proprietary food and drug trades Almost every one of these is advertised as just the thing for the patient, if not during the attack itself then during convalescence or during the "post influenzal state" And a good many new "tonics" have been rushed upon the market by quite reputable firms, whose travellers have been working overtime and earning fat commissions There was already a spate of new tonics before the influenza came, for what with more and more vitamins, and more and more hormones, to play with, the combinations and permutations became quite headachey I was recently found by a colleague to be in the "post-influenzal state" myself, and I admired the diagnostic acumen which led him to this (correct) conclusion I had asked him the same question three times during our consultation "Leave it to me," he said, "I know just the thing for you—wonderful" And on the way out of the house he used my telephone to order (at my expense) a bottle of tablets which was delivered within the hour "Two or three, after meals, three times a day" Natural curiosity led me to read the label. The "formula" must have made the Easton's Syrup on the neighbouring shelf blush for shame Iron, Copper, Manganese, Zinc, Nickel and Cobalt were the chief ingredients I thought I knew something about hæmatinics and nerve tonics, but nickel and cobalt ? This comes, I reflected, of not reading the journals and keeping myself abreast of the times. Ah ! here s the new edition of the Extra Pharmacopœia, the 21st, just arrived. I turn up the index to that encyclopædic work, the pages of which have often caused us to marvel—so compendious and yet so accurate. ' Nickel, Detectn. and Detn. of. ' Reagent for Albumose. Cobalt ? No mention of cobalt. The wholesale chemist is in advance of the Extra Pharmacopœia But I have swallowed the first two tablets and who knows that if I go on with them *something* may not soon be known of the pharmacology of cobalt and/or nickel ?

I *think* it was this same colleague who when I had suggested that a plethoric patient might benefit from three grains of blue pill once a week after his dinner and a saline next morning asked me the patient having left the room, By the way what is blue pill ?

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM A ROVER

II

FROM considerations of prestige in respect of the individual doctor it is an easy transition to pass to the prestige of the profession as a whole Many of us lament that this is not what it was and is lower than it might be If we believe that it is good for the public, and also good for us, that the status of medicine should be high it behoves us to inquire where the fault lies It has been said that nations get the governments they deserve, and it might be said with equal truth that society gets the doctors it deserves But might it not also be said that medicine gets the public it deserves? For inasmuch as the doctor is, or should be, a man or woman of culture above the average in the nation, and is specially trained in both the art and the science of medicine, he (I shall assume both sexes when for convenience, I use this word) has every right to lead, to teach, and even to dictate in his particular sphere,

* * *

I believe that if he put this value upon himself and upon his services the public would not only respect him more, it would accept his guidance and his dictation with relief and with benefit As it is, the public persuades itself that it is as knowledgeable in matters concerning its health as the doctor himself, and, in many instances, only needs his services when it is out of its depth by grave illness, or when it sees that it can batten upon his known generosity in the disposal of his time and energy and even his blood

* * *

If there is one reason more than another for the lack of respect for the doctor as a leader in his proper sphere it is probably the fact that he "gives" too readily in the face of fads and cults and transient notions Instead of refusing to traffic with pseudo science and pseudo art, protesting against them and warning the public that salvation does not lie in these directions, he joins in the worship of the false gods, not only passively but too often actively Oft times he fears that not to do so will proclaim him "narrow minded" Whereas it is just this sort of narrow mindedness that constitutes one of the doctor's chief duties to the public After all, it is only he who can detect the cloven hoof and, when he sees it, it is in the public interest that he shouts the fact from the house tops

* * *

If we look down the lists of patrons and committees of many of the health "movements" that originate in the vanity and half-knowledge of retired service men, priests, financiers, and litterateurs we find the names of medical men in abundance The public does not know, as we do, that the same names recur in a number of these lists and that the names have no meaning for us except that they belong to colleagues of whom we are heartily ashamed, men with anti minds, who have an itch for the irregular and the unorthodox Charity leads us to say that they "believe" in the queer doctrines they support, but even if they do, it is our duty to proclaim them as anti social Examples would fill my 'Grains and Scruples" pages, but here is one, to hand this week. "The Health Education and Research Council" has, as one of its professed objects, "the encouragement and support of methods of healing which are dissociated from experiments on animals such as Homœopathy, Herbalism, Nature Cure, Osteopathy wireless wave therapy, vegetarian and fruitarian systems of dietetics " Some thirty legally qualified British doctors are listed as "advisory members" and their names are printed at the head of the circular letter Accompanying the letter is a book with the title "Cancer the failure of modern research" The "blurbs" printed on the paper cover are extracts from two reviews which appeared in a couple of medical journals One of these states that "the book throws a flood of light on the absolute failure of modern cancer research." The other says, "this is an excellent exposure of the failure of modern cancer research which we have long recognised to be conducted on entirely wrong lines" Unfortunately we are not told what are the right lines along which cancer research should be conducted.

* * *

In parentheses under the main heading of this circular letter occur the words "International. Dissociated from Experiments on Animals" Which seems to suggest that these are our old friends the Anti Vivisectionists in a new guise And, on reflection, we are confirmed in this view by some of the names on the executive committee I wonder if it has occurred to any of the doctors on the advisory board that if they neglected to use antitoxin in a case of diphtheria nowadays they would almost certainly incur a charge of criminal neglect? But since martyrdom has its own special attraction for some folk this consideration, after all, may not have been lost sight of.

* * *

The influenza epidemic has given a great fillip to the proprietary food and drug trades Almost every one of these is advertised as just the thing for the patient, if not during the attack itself then during convalescence or during the "post-influenzal state" And a good many new "tonics" have been rushed upon the market by quite reputable firms, whose travellers have been working overtime and earning fat commissions There was already a spate of new tonics before the influenza came, for what with more and more vitamins, and more and more hormones, to play with, the combinations and permutations became quite headachey I was recently found by a colleague to be in the "post influenzal state" myself, and I admired the diagnostic acumen which led him to this (correct) conclusion I had asked him the same question three times during our consultation "Leave it to me," he said, "I know just the thing for you—wonderful." And on the way out of the house he used my telephone to order (at my expense) a bottle of tablets which was delivered within the hour "Two or three, after meals, three times a day" Natural curiosity led me to read the label. The "formula" must have made the Easton's Syrup on the neighbouring shelf blush for shame Iron, Copper, Manganese, Zinc, Nickel, and Cobalt were the chief ingredients I thought I knew something about hæmatinics and nerve tonics but nickel and cobalt? This comes I reflected of not reading the journals and keeping myself abreast of the times. Ah! here's the new edition of the Extra Pharmacopœia the 21st just arrived. I turn up the index to that encyclopædic work the *pages of* which have often caused us to marvel—so compendious and yet so accurate. Nickel Detectn. and Detn of. Reagent for Albumose Cobalt? No mention of cobalt The wholesale chemist is in advance of the Extra Pharmacopœia But I have swallowed the first two tablets and, who knows that if I go on with them *something* may not soon be known of the pharmacology of cobalt and/or nickel?

I *think* it was this same colleague who when *I had suggested that* a plethoric *patient* might benefit from three grains of blue pill once a week after his dinner and a saline next morning asked me the patient having left the room, By the way what is blue pill?

CORRESPONDENCE

AFTER-CARE IN PULMONARY TUBERCULOSIS

To the Editor of THE LANCET

SIR,—I read with great interest Dr Trail's Mitchell lecture published in your issue of Jan 30th Dr Trail mentions that the year following the patient's discharge from sanatorium is a most vital one and that "not the least of the advantages to the case of artificial pneumothorax lies in the continual and expert supervision for a period of some three years following the induction," and goes on to say that "until such benefits are universally provided we must continue with the present results of sanatorium treatment"

I agree that this expert supervision is most valuable, but would point out that the dispensary provides this for all cases of tuberculosis, ex sanatorium patients, and others, for an indefinite period I wish that Dr Trail had placed greater stress on the importance of the social factor After many years' experience among that type of patient who, for financial reasons, insists on returning to work as soon as discharged from sanatorium, no matter how unsuitable the work may be, or who failing to do so drags out an unsatisfactory existence in unsuitable environmental conditions with an insufficient income, I am convinced that this country will never reap full benefit from the time and money spent on sanatorium treatment unless more money is spent on really useful care work Most valuable work could be done in this direction and the prognosis of many cases vastly improved if adequate funds were available

I am, Sir, yours faithfully,

R SEPTIMUS WALKER

Paddington Tuberculosis Dispensary
Talbot road London, W , Feb 8th

A SURVEY OF DIETS

To the Editor of THE LANCET

SIR,—The article in THE LANCET of Jan 30th which deals with the Medical Research Council Report No 218 is somewhat misleading, this may in part be due to the way in which the results of the surveys are presented in the actual report It was the calcium intake "per man" that was found to be over 0 68 g This conventional "man" unit may be justifiable in calculations of calories or even of protein, but is quite inapplicable when calcium is concerned, since the calcium requirements of growing children are as high or higher than those of adults According to the Stiebeling scale (which allows 0 68 g daily per adult man), the calcium requirement of a family consisting of man, wife, and three children, aged 3, 6, and 8 years, is 4 56 g, the "man value" of the family is 3 33 If the daily calcium allowance is only 0 68 g per "man," the family intake is only half the requirement, to be adequate the allowance "per man" must be 1 4 g daily This family coefficient method is equally inapplicable in the case of milk, and to a less degree in the case of iron

The article also states that 'in every group the amount of first class protein was considered to be above the minimum required." Actually all that is claimed in the report is that the fraction of the total protein that was derived from animal sources was over one third This seems an odd criterion of the adequacy of a diet A man might be only taking 10 g of protein and yet over half of his intake be first class protein Actually the average daily first class protein of 119 out of 259 families studied was under the level, 37 g, proposed by the Advisory Committee on Nutrition, in only 22 families was it over the standard, 50 g, of the Committee of the British Medical Association

I am, Sir, yours faithfully,

Bishops Stortford Feb 6th JOHN MARRACK.

STANDARD OF ARMY RECRUITS

To the Editor of THE LANCET

SIR,—I have read with interest Mr Flemming's letter in your issue of Jan 2nd He concludes his letter by asking whether candidates suffering from varicocele, who seek acceptance in Government service, are rejected "on observation or on tradition." Perhaps the correct answer is the latter—i.e, "we do it because we have always done it" Some of us, in our student days, have been warned to avoid meddlesome midwifery To day I regard the operation for cure of varicocele as meddlesome surgery

A varicocele, presumably, is a response of nature during the changes and development at the time of puberty If so, why surgical interference? Does one ever hear of a patient in the thirties complain of varicocele? I am unable to recall a single case of severe local injury or hæmorrhage as a result of normal athletic exercises in those possessing a varicocele But I have seen a number of cases requiring operation for the cure of secondary hydrocele following the operation for varicocele

Mr Flemming refers to varicocele as "a harmless anatomical condition" I agree If this be true, surely then varicocele is not a cause for rejection of candidates for any service

I am, Sir, yours faithfully,

PHILIP A HALL,

Feb 3rd Consulting Surgeon to the Royal Air Force

REST HOUSES FOR RHEUMATOID ARTHRITIS

To the Editor of THE LANCET

SIR,—I should like to express my entire agreement with the views so ably put forward by Mr W A Cochrane in your issue of Feb 6th, as well as in your leading article in the previous number I note with satisfaction Mr Cochrane's use of the term "medical orthopædist", it is too often forgotten that orthopædics is a branch of medical science calling for physicians as well as surgeons In the management of arthritis, if the physician has been given early and adequate opportunities for proper physical treatment, surgery will rarely be required The keynote of such treatment is rest combined with proper diet in suitable surroundings, together with mild physiotherapy in the form of massage, exercises, and perhaps sunlight. The model to be followed is the tuberculosis sanatorium linked up with out patient clinics in the large towns where the cases could be selected in the first instance and where after discharge from the sanatorium proper supervision and control could be exercised

While it may be necessary to rely to some extent on private generosity for the provision of such sanatoria and for the furtherance of research, in view of the drain upon the working capacity of the country due to rheumatic diseases and the present policy of the Government which aims to improve the physical condition of the people, the public purse should be called on for a large share in the cost of maintenance and ultimately for all. It is only fair to point out that a scheme for linking up out-patient clinics hospitals and sanatoria for the treatment of chronic diseases such as rheumatism was outlined about eighteen years ago by Lord Dawson of Penn and has been further developed since by Dr W S C Copeman and others including the present writer Public opinion is slow to arouse, but the idea is steadily gaining in popular support. An appropriate quotation from the Third Rheumatism Review issued by the editorial committee of the American Association for the Study and Control of Rheumatic Diseases may perhaps be permitted— The slogan of the few is becoming that of the many: something must be done to solve the enormous problem that is *rheumatism*

I am Sir yours faithfully

Buxton Feb 6th CHARLES W BUCKLEY

ANACIDITY AND LONGEVITY

To the Editor of THE LANCET

SIR,—Lerman Pierce and Brogan[1] observe that up to the age of sixty five there is a definite correlation between age and the incidence of gastric anacidity—i.e. the latter increases with age Beyond the age of sixty five however the number of anacid cases decreases

It would seem that there are only two possible explanations of this noteworthy observation. The one is that gastric anacidity disappears in aged people in whom it has previously been present This is unlikely because if gastric anacidity is favoured by some condition in old age as the statistical data suggest an improvement of this condition due to further ageing could not be expected. Consequently it is more probable that the only other possible explanation holds true according to which there is a comparatively increased death rate among those who are afflicted with gastric anacidity Further statistical studies are required to test the validity of this explanation.

I am Sir yours faithfully

New York City Jan 27th. EUGENE FÖLDES

HEARING AIDS

To the Editor of THE LANCET

SIR —I am much interested in the special article on hearing aids in your issue of to-day because it recalls to me my own experience when investigating their value in schools for the deaf more than twelve years ago Dr and Mrs. Ewing and Dr Littler found that of 236 deaf children 140 or more than half could benefit educationally by hearing-aids. In 1924 I was asked by the then school medical officer of the London County Council to undertake an investigation at the instance of the medical department of the Board of Education into the question of How far children in the hard-of hearing class can benefit by the use of special apparatus (see *Brit J Child Dis* 32 261) This work I accomplished in conjunction with Mr W H. Pettifor in a class then existing at Stanley street Deptford.

Thirty-seven scholars (20 boys and 17 girls) were examined of whom 35 were deaf from middle-ear conditions, 1 was born partially deaf and 1 was deaf from meningitis Of these 5 children had sufficient residual hearing to enable them to profit from special oral teaching and were therefore not included in the test Of the remaining 32 28 (87 5 per cent) were improved and 4 not improved

What was specially interesting from the point of view of easy working of the method was that the great majority of these good results were obtained with one type of instrument which clearly established the benefits which would accrue from installing such an aid in the class.

In my report I suggested that an experimental outfit should be installed in the class tested for one year to make certain as to its practical utility in teaching while an extended investigation was conducted at other centres At the same time I drew attention to the fact that in the United States aids of this kind had been for some time used successfully in their deaf and partially deaf schools. In addition I found a philanthropic friend who promised to be responsible for the cost of the installation. To my bitter disappointment my recommendation was turned down by the London County Council, its rejection being due (as was later made public) to the act of one lay official who it being nobody's special business to invite him to see the tests, was unfortunately not notified officially although he was asked unofficially This display of petty jealousy delayed the advent of a most valuable aid to deaf teaching for some ten years It is, therefore the more gratifying to know that later workers have confirmed my conclusions.

I am Sir yours faithfully

Wimpole-street W Feb 6th. MACLEOD YEARSLEY

RENAL TUBERCULOSIS

To the Editor of THE LANCET

SIR,—In your last week's issue, in commenting on our work you state (p 329) that treatment of the tuberculous kidney is in fact following in the wake of treatment of the tuberculous joint and that operation, if it is performed, is to be regarded as an unwelcome necessity Tuberculosis of a joint and of a kidney are the same in that they are both metastatic hæmatogenous lesions both should be subjected to the same sanatorium régime but they differ in the essential factor that local rest can be given to a joint but cannot be given to a kidney We have at present insufficient material on which to base an opinion about the healing of an ulcero cavernous renal tuberculosis, but it seems likely that these gross lesions do not heal except by autonephrectomy due to occlusion of the ureter In this case cessation of renal function is analogous to therapeutic rest of a joint Moreover if secondary infection of a tuberculous joint occurs healing by sanatorium treatment and other means is delayed if not prevented It remains therefore to ascertain what influence secondary infection has on the healing of renal tuberculous lesions

So far as we have been able to ascertain in our series of cases renal disease was nearly always bilateral One of the great benefits of sanatorium treatment lies in healing the minor lesion and rendering the inoperable patient operable Finally may we endorse the view that early diagnosis and sanatorium treatment of renal tuberculosis both before and after operation are essential if the prognosis is to be improved.

We are Sir yours faithfully

RONALD REID

M C. WILKINSON

MORE AND SAFER MILK

To the Editor of THE LANCET

SIR,—In your paragraph last week on More and Safer Milk you report the Minister of Health as having said that "the more the consumption of milk was increased the more important did it become to secure the safety of the supply" Most doctors would agree to this but how many are doing anything to implement it? Everywhere the public is being urged to drink more milk or to supply it to others The under five population and nursing mothers are likely to follow school children as subsidised recipients If a voice whispers "what of milk borne disease?" lay bodies brush it aside, saying "that is the doctors' business" It is the doctors' business but so few trouble to mind it They feel that the Ministry of Health should see to that The Ministry is up against the Treasury and the Treasury must consider agricultural interests too So the ball rolls from one to another with the net result of an increasing subsidy for unsafe milk.

Is not this an occasion when general practitioners might actively support medical officers of health by demanding that subsidy and safety should march together?

I am, Sir, yours faithfully,
ESTHER CARLING

Berks and Bucks Joint Sanatorium Oxon, Feb 9th

WANTED A HOSPITAL EMBLEM

To the Editor of THE LANCET

SIR,—Now that the matter of a hospital emblem in connexion with a Hospital Week in London is under consideration, it might be opportune to ask the College of Heralds to submit designs for a hospital flag which in miniature might be adopted for Hospital Week in London It would be a pity to have one emblem for Hospital Week in London and a flag of another design flown by hospitals on their fête days and on State occasions The council of the British Hospitals Association have had the matter of a hospital flag up for consideration and it is mainly the cost that has so far deterred them from taking steps to meet the wish expressed by several hospitals for a properly designed flag

I am, Sir, yours faithfully,
R H P ORDE,
Hon Secretary The British Hospitals Association.

Grosvenor-crescent S W, Feb 9th

RADIOGRAM AND RADIOGRAPH

To the Editor of THE LANCET

SIR,—In your issue of Jan 30th Radiogrammarian writes "*roentgenograph* and *roentgenogram* are too distinctively American to gain ready acceptance in this country" Far from being "too distinctively American" those words are not even distinctively American They, and the other derivatives of *roentgen* are used almost exclusively in the Scandinavian and German literature *Acta Radiologica's* preference for *roentgenology, roentgenogram,* &c, is well known, and there is, in my opinion, much to commend it Surely it is not inappropriate to name a science after its founder, or an X ray photograph after the scientist who made the first one?

Finally, why not be as international in our terminology as possible? If American, Scandinavian, German, and other roentgenologists prefer *roentgenogram,* &c, then I think that that is an excellent reason for using them in preference to the derivatives of *radio*

I am, Sir, yours faithfully,

Feb 4th ROENTGENOLOGIST

OBITUARY

S HARRY HARRIS, M.D Sydney, F R A C S

THE announcement of the death of Dr Harry Harris of Sydney, New South Wales, will have been read with deep regret by his fellow urologists Only last year he spent several months in this country, taking part in discussions, and demonstrating in our theatres his operation of prostatectomy with primary closure of the bladder At first condemned here, much to the disappointment of its originator, Harris's method of prostatectomy has steadily gained in favour and has been widely adopted Actually the first description of it appeared in a paper read at the Australasian Medical Congress held in Dunedin in March, 1927 Like many important original papers, however, it attracted little attention, and Harris's visit to Europe in 1935 was in the nature of a crusade against what he regarded as unreasonable prejudice He was determined to demonstrate the advantages of his method, and although he was in indifferent health, he worked with such industry that there were few who had not the opportunity of watching him operate His enthusiasm was infectious and he made many converts It will be a gratification to his friends that he lived long enough to see his work vindicated. It was no light task for a surgeon living in Australia to drive home his claims against a definitely hostile school of opinion but few obstacles could withstand his determination The majority of British genito urinary surgeons are now prepared to admit that although his technique is unlikely ever to be used as a routine, it has gained an important place in prostatic surgery

Another operation with which Harris's name is connected is that of renal sympathectomy For over eight years he carried out denervation of the renal pedicle and was therefore in a position to speak authoritatively of its scope and its limitations The condition in which he found that renal sympathectomy gave the most favourable results is the one for which he coined the somewhat awkward term of "renal sympathetico tonus" This condition of overaction of the sympathetic nerves of the renal pedicle he compared to Hirschsprung's disease of the large bowel, and his views on it were fully described in an article he published in these columns two years ago

Harris was educated at Sydney Grammar School, of which he was captain in 1900 He represented Sydney University at cricket, and after a resident post at Sydney Hospital entered general practice In 1914 he joined the staff of the Lewisham Hospital and from 1918 onwards he was purely a consultant Dying at the comparatively early age of 56, he leaves a widow and one son Two of his brothers are members of the medical profession

ANDREW DANIEL CLINCH, M D Dubl

Dr Clinch, who died on Feb 2nd, was formerly a medical inspector of the Department of Local Government and Public Health, and was one of the best known and best liked medical men in Ireland.

Educated at Belvedere College and Trinity College Dublin he qualified in 1898 and a few months later was appointed dispensary medical officer of the Clondalkin district Co Dublin whence he was later transferred to the Grand Canal-street district, Dublin During the war he served in the Royal Army Medical Corps in France. Shortly after his return to Ireland he was made a medical inspector of the Local Government Board, and he retained that position until his retirement three or four years ago As a Government medical inspector writes our Dublin correspondent, Clinch was an officer of singular ability Possessed of robust and shrewd common sense tactful kindly with a thorough and tolerant knowledge of his countrymen he succeeded in keeping up a higher standard of efficiency among the men and the institutions under his supervision than might have been effected by a more stern disciplinarian. Since his retirement from the public service he had taken trips to many parts of the world as a ship surgeon Outside his professional work Clinch was best known by his life-long interest in Rugby football. As a student he played for Dublin University and was given his international cap as long ago as 1892; when no longer eligible to play for the University he played for and was captain of the Wanderers Club Between 1802 and 1897 he played in ten international matches and in 1806 he toured South Africa with an Irish team. When his playing days were over he became one of the most active workers of the Irish Rugby Union on whose councils his common sense tact and popularity made him a power Of late years his health had failed, but his death came unexpectedly He had indeed been present to watch his favourite game and to join in a presentation to an old colleague only three days before his death.

Clinch had a great gift of making and keeping friends. His fellow-students of forty years ago found him the same at 65 as at 25 Meeting him at intervals of perhaps years there was no change in the firm hand grasp and none in the gentle voice and the kindly smile which went so unexpectedly with the massive and powerful physical frame.

CHARLES JAMES LEWIS M.D D.Sc F.R C P Edin

On Saturday last Dr Lewis died at Birmingham where much of his professional life had been spent and where he was emeritus professor of public health in the University Before going to Birmingham however he was for many years in practice in Edinburgh and it was in Edinburgh that he got his medical education His undergraduate career was distinguished he was president of the Royal Medical Society graduated with first-class honours and gained the Wightman prize He became a member of the general council of the University and in 1895 was elected a fellow of the Royal College of Physicians of Edinburgh In 1000 he took a science degree in public health and received the Gunning prize In the following year he also carried off the Parkin prize for an essay on the curative effect of carbonic acid gas and other forms of carbon in cholera, for different *forms of fever* and other diseases" and about the same time he was writing on typhoid bacilluria and the purification of drinking water He was now well launched on a public health career holding teaching appointments at the school of medicine of the Royal Colleges and elsewhere and an examinership at the College of Physicians With Dr Balfour he was co author of Public Health and Preventive Medicine and his medical interests ranged from the bacteriology of the nose and of the atmosphere to problems of demography It was especially as a bacteriologist interested in public health that some thirty years ago he was appointed to Birmingham, where he became university lecturer and chief bacteriologist under the professor of pathology Dr Leith. A colleague who joined him as junior in 1907 writes Dr Lewis was very deaf and it was said that increasing deafness had obliged him to give up a lucrative general practice and take to bacteriology for his livelihood. For some years we worked together often in the same room, and I came to know him very well. He was a most gentle kind and courteous man I do not recollect him ever complaining of anything or saying a harsh or unkind word. In his work he was scrupulously honest and in his research he recorded everything that told against him just as carefully as the facts which favoured his opinions I do not remember him ever accepting the findings of anyone in the laboratory He insisted on seeing and doing everything for himself For a great deal of his original work others got the credit Dr Lewis seemed quite indifferent to fame or money At that time his favourite recreations were golf and bridge. He was a very keen golfer and he seemed to spend every Sunday at the Sandwell Park Club where he played regularly till ill health and weakness made exertion impossible He was a most lovable little man rather diffident in most things but most unwaveringly obstinate in his insistency on accuracy and truth in his laboratory work and in his records and writings

Dr Lewis's inquiries at Birmingham including observations on the non lactose-fermenting bacilli and on Morgan's bacillus were published in reports to the Local Government Board. After the late war he was made director of the public health laboratories of the University and associate professor of public health and on his retirement a year or two ago his valuable services were recognised by conferring on him the title of emeritus professor

MAX SCHLESINGER M.D Budapest

In Dr Max Schlesinger who died on Feb 4th at the age of 30 medicine has lost a research worker of brilliant promise and considerable achievement A Hungarian by birth, he was greatly attracted by physics and mathematics After taking his medical degree at Budapest he turned his attention to the physical properties of viruses and bacteriophages and for a number of years did remarkable work under Prof Bechhold at Frankfurt A year ago he came to this country and after a few months at the National Institute for Medical Research was appointed to the staff of the Imperial Cancer Research Fund.

Among the notable results achieved by Schlesinger was the successful application of the method of centrifugation to the study of the particle sizes of viruses and bacteriophages. Recently he evolved a simple method whereby the Sharples centrifuge might be used for this purpose He also conducted extensive studies on the purification of phages by a method involving fractional filtration and centrifugation A weighable amount of phage was finally obtained and studied as regards its chemical composition and its optical and staining properties.

Bishop Auckland Cottage Hospital.—Sir George Gillett commissioner for the Special Areas has decided to make a grant of over £10 000 towards the cost of rebuilding and re-equipping this hospital

PARLIAMENTARY INTELLIGENCE

FEEDING OF SCHOOL-CHILDREN

In the House of Commons on Feb 3rd Mr SHINWELL moved —

"That, in view of the disquieting reports regarding the physical condition of children, this House is of opinion that, out of moneys provided by Parliament provision should be made for supplying, in addition to milk, at least one meal per day to every child attending an elementary or secondary school"

The question of under feeding and improper feeding was, he said, closely related to the question of health The Labour party would never be content until all children, at school or otherwise, irrespective of parental income, were every day in the year provided, not with one meal, but with all meals that were required for their sustenance They recognised, however, that there were some practical difficulties in the way They must raise wage standards to a much higher level and unemployment must disappear, they must reorganise production and distribution of foodstuffs before that was attained But meantime they wanted an assurance from the House of Commons that at least one substantial meal a day would be provided for children attending school Although some improvement in health was manifested among school children, the position was far from satisfactory In his annual report the chief medical officer of the Board of Education said —

"The reports of school medical officers throughout the country generally do not suggest that there has been any deterioration in the nutrition of school children Where statistics relating to heights and weights are given there is almost invariably an increase shown compared with the statistics of previous years"

But the chief medical officer added —

"The question may, however, be not so much as to deterioration but whether the degree of progress is as satisfactory as it might be That good nourishment does exist in certain areas and in certain sections of the population is hardly to be contested There are areas in which severe depression, continued for many years, has left its mark"

There was, of course, considerable variation in the condition of school children in different parts of the country In the special areas the deterioration was most marked In Hebburn, for example, according to this report, a substantial increase in the measure of deterioration had recently been recorded Dr Burn, the medical officer who went to that district not long ago, said —

"I have tried to examine the children in an unbiased way, and with not too exacting a standard in mind Perhaps previous experience of areas where unemployment is less severe colours my impression, for I must admit that the state of nutrition of Hebburn children is decidedly inferior to that of the children of more fortunate areas"

Then Dr Burn went on to say —

"Our children bear on their bodies the marks of the economic hardships of recent years"

Independent investigations had recently been undertaken throughout the country by teachers in actual contact with the children In Durham county several teachers had declared that there seemed to be a remarkable difference between children coming from homes where there was prolonged unemployment and those where wages were regular, that many of the children were thin and starved looking and that in physique, mental alertness, and ability they were much below the standard of five years ago and were decidedly backward in lessons and easily tired One head master stated that, in his own school of over 400 children at least one-third showed the need for more food. He went on to say —

'The provision of milk has prevented the situation from becoming worse, but many show signs of distress in spite of the milk ration"

It was too often thought that under nourishment was confined to the special areas, but that was far from being true In the London area, 189,203 school children were medically examined during 1935, only 32,934 were in excellent health The ill-health of the remaining five-sixths was regarded as due mainly to under nourishment Opinions were expressed in previous reports of the Board of Education in relation to the survey of 3000 unselected children between the ages of two and six Excluding dental and eye defects, 27 per cent of them suffered impairment of health Admittedly, more and better food could effect a substantial change in the health and physique of school-children. Sir John Orr had stated that the result of tests on children showed that improvement of the diet in the lower groups was accompanied by improvement in health and increased rate of growth

The Labour party regarded the existing provisions as hopelessly inadequate Two conditions were laid down before meals could be provided The incomes *of parents must not go beyond a certain scale* The other condition was that, irrespective of income, it must be firmly established, as a result of medical inspection, that a child was unable, because of its physical condition, to absorb education Both these conditions were highly objectionable If it was found necessary to impose conditions he would rather have the income condition than the other If they were to establish physical fitness, and if it was agreed that sound feeding was the basis of physical fitness, the provision of meals, whether of milk or otherwise, should form part of the educational system of this country

The first objection to the proposal was on the ground of cost No matter what the cost, no price was too high to pay for the assurance that school children were being properly nourished But the Minister had exaggerated the cost His estimate was based on the retail price of milk at about 1*s* 4½*d* a gallon But they knew that millions of gallons of milk were sold in this country for manufacturing purposes at round about 5*d* a gallon. Clearly, if those engaged in the milk-producing industry had an assured market, they could afford to sell the milk at a much lower price If the Minister regarded the cost on that basis as too high, his conception of the needs of school-children was quite different from that of the Labour party

In spite of the milk ration children required more and better food It had been firmly established that thousands of children went short Where there had been prolonged unemployment parents were unable to pay for the meals, and if, the local authorities because of heavy rating burdens, were unable to provide the funds, the State must come to their assistance The Minister had assumed a cost of 5*d* per meal, but in Bradford, where they had been providing free meals to school children for many years, the total cost of foodstuffs, overhead charges cost of canteens and of transport was 3½*d* per meal In Edinburgh the cost of the food was less than 2*d* per meal It was very doubtful whether 3*d* is required in order to make up the overhead charges In London they learned that the cost of the meal alone was less than 2*d* If meals were provided regularly there would be some reduction in the amount of disease amongst school-children The whole nation would gain in health, in vigour, in physique, and, above all, in food production, if this motion was accepted

AN AMENDMENT

Miss CAZALET moved the following amendment —

"That this House welcomes the measures taken by the Government to promote the physical welfare of children, recognises the beneficial results already achieved, as shown by the annual reports of the chief medical officer of the Board of Education and hopes that where necessary the powers already possessed by local education authorities for the purpose will be more fully utilised

It would she thought be a great waste of public money to insist that all children should be fed irrespective of whether they required it or not, whether their parents wished them to have it or not and whether they were being properly fed in their own homes School medical officers throughout the country did not suggest that there had been any deterioration in the nutrition of children report after report afforded testimony to improvement Walsall Eccles, Wakefield Cumberland Cannock and a host of others all showed there had been hardly any malnutrition The better economic position of the country and the decrease in unemployment played no small part in the general health and physical well being of the children. The great milk scheme had been described as the largest experiment in supplementary school feeding that the world had ever seen. Nearly 3 000 000 children were benefiting under it and she believed nearly 400,000 were receiving free milk daily With regard to actual meals, it was the function of the education authority to see that all children who attended school were in a fit and proper condition to take advantage of the education In London there was not a single child whose education needed to suffer because of under-nourishment or malnutrition, and she believed that that was the case in many parts of the country Nearly double was being spent on meals alone to-day compared with 1930–31 It was true that some of the tables of the chief medical officer's report showed that things were not so satisfactory in certain areas where there was a higher percentage of children in categories C and D than any of them would like to see She asked the Government to ease the situation in those districts where education authorities, owing to poverty were not able to take full advantage of the powers they possessed

PARLIAMENTARY SECRETARY'S REPLY

Mr Geoffrey Shakespeare said that no one could read the chapter on nutrition and school feeding in the annual report quoted by Mr Shinwell without being impressed by the unanimity of school medical officers that there was no general deterioration in health in spite of economic strain. Anyone who compared the state of children now with the state ten years ago their appearance their alertness and physical well being must see the improvement that had taken place There were six weapons on which the Government relied to counter the effects of the economic strain.

(1) There was the increasing attention given to the state of nutrition in the routine inspections and the assessment of the state of nutrition on more careful and uniform lines

Mr Cove That is by the doctors —Mr Shakespeare: Yes

Mr Cove We do not know what the standard is

Mr Maxton: And that is once in five years

There was also the growing practice of arranging special nutritional surveys at short periods

(2) The second weapon was the increasing provision of supplementary nourishment whether milk meals or free meals for children whose parents were unable to pay

He had chosen three years to show how steady had been the advance In the year 1924–25, 132 local education authorities provided for some 70 000 children 7 500 000 free meals whether they were solid or milk meals In 1930–31 153 local education authorities provided 185 000 children with 27 000 000 free meals and in 1935–36, 235 local education authorities provided 470 000 children with 86,500 000 free meals In other words in that interval the number of local education authorities providing free meals had grown from 132 to 235 the number of children fed had increased sevenfold the number of meals provided had increased 11 times and the cost had quadrupled Clearly there had been great progress in the provision of free supplementary nourishment In spite of the fact that distress to-day was less than it was in 1931 there were three times the number of free meals provided to-day as compared with 1931

Mr Shinwell had raised the question of Circular 1443 of December 1935, which was issued in agreement with the Association of Education Committees That circular made plain what was the qualification for free extra nourishment and laid down that it covered the cases of all children who needed it and were unable to pay for it Such provision could be made if a child showed the slightest symptom of inability through lack of food, to profit by its education It was not left to nutritional surveys to take note of these symptoms. It was made plain that teachers and others who were in constant touch with the children could make recommendations on that basis The Board of Education did not lay down any income scales but the local authorities laid down a scale which assured that the children of those who were employed at low wages, or who were unemployed came within the category of those who could be provided with free meals

Mr Shinwell: That is perfectly true but only if after examination by the school medical officer children are found to have symptoms which indicate that they are unable to absorb education.

Mr Shakespeare: We look at it of course from an educational point of view Where through lack of food the children are unable to profit by the education given free nourishment should be provided

Mr Maxton: You say the teacher may be the judge of that

Mr Shakespeare: The teacher may recommend a case as coming within that category and the child is then examined by the school medical officer Education now included physical training and if a teacher thought there was the slightest symptom of a child not being able to profit by physical training on the ground of lack of food free extra nourishment could be provided

(3) The third weapon on which they relied was what was commonly called the milk-in-schools scheme and over 2 500 000 children had been provided for by facilities which covered school attendance of over 90 per cent. of the elementary school population He thought it was true that this was the greatest single nutritional experiment in the world They had only to read the glowing account of Dr Petrie in the chief medical officer's report to see how very widely this scheme had benefited the children. The Government would like to see many more children enjoy the benefits of it With that end in view they sent a skilled investigator last year to find out why no more than 50 per cent of the children took this free milk His report confirmed what had been his own impression since he had been at the Board, that non participation was due either to indifference on the part of the parents or more usually a distaste for milk on the part of the children

(4) The fourth weapon on which the Government relied was the promotion of physical welfare by improving the facilities for and the standard of physical training in the schools

(5) The fifth was the provision of meals at school canteens where there was a local demand Indeed, in connexion with the reorganisation of the education services which was actually going on the senior schools had as a rule school canteens at which the children could get at least a good dinner at a reasonable charge

In Kent some 63 public elementary schools had canteens serving dinners to 5000 children In East Sussex some 25 elementary schools served 1800 children and in East Suffolk 15 schools served 1208 children The charge in the canteen arrangement for meals varied from 1s to 1s 8d. per week. That charge did not as a rule include overhead costs

(6) Another important point was the instruction of boys and girls in the new science of nutrition. It took the form of teaching cookery, and 91 per cent of the girls, aged 11 years or over, who received instruction in cookery, also were instructed in nutrition They were taught such matters as food values, the cost of food, the value of meals, and what were the best foods to cook There was much ignorance among all sections of the community as to what constituted a balanced diet

He would conclude with some figures in relation to the physical welfare of children given in the report of the chief medical officer In his survey children were divided into four categories, A, B, C and D, according to whether their nutrition was excellent, normal, slightly subnormal, or bad Out of 1,687,000 children examined in England and Wales in 1935, 14 6 per cent were found to be excellent, 74 1 per cent were normal, 10 6 per cent were slightly subnormal, and 0 7 per cent were bad In regard to London out of 189 200 children, 152, or 0 08 per cent, were bad, and 10,646, or 5 67 per cent, were slightly subnormal The rest were satisfactory It did not follow that if a child was slightly subnormal the primary cause was lack of food The cause might be environment, like bad housing and lack of sleep, or functional It might be the result of disease, infectious or otherwise When he asked the doctor in charge of the experiment at Aldershot recently on the sub standard recruit, to what he attributed the improvement in the physical welfare of those sub-standard recruits, he said that clearly good nutrition and intensive physical training were factors, but that in his judgment the regular hours of routine to which the recruits were subjected was a factor no less important

The amendment was carried by 167 votes to 124

PHYSICAL TRAINING OF THE NATION

In the House of Commons on Feb 8th Mr **Oliver Stanley**, President of the Board of Education, moved a supplementary estimate for education services in England, Wales, and Scotland Dealing with the Government's plans for physical training, he said that the new scheme had had a most encouraging response from the general public It was designed to deal with physical training and recreation, it was not and never had been meant to be a plan to deal with nutrition Physical training and nutrition were complementary, not exclusive No one would regard physical training and recreation as a substitute for good nourishment, but to give the impression that the great mass of our people were so underfed and so weak from the lack of nutrition that they were unable to derive enjoyment or profit from physical training in games was a grotesque mistake Mr Stanley then explained the scheme in detail, and said that Lord Aberdare had consented to become president of the Advisory Council

Sir **Francis Fremantle** said it was true that to get the best use out of physical exercises there should be proper nutrition and medical and dental attention at school It did not follow, however, that they should wait until they had perfection before they made any advance with physical training The medical profession as a whole would be out to help the Government in their scheme It was essential that there should be a considerable change in medical education which in the past, had been the training of doctors in hospital to treat those who were sick Students had not been properly taught this ideal of producing healthy bodies

Sir **Ernest Graham Little** asked what methods were going to be adopted to see that positive harm was not done by the physical training of persons who were under-nourished He pointed out that the voluntary associations, which were being entrusted with so much of the work under the Government's scheme were completely unequipped to undertake medical service

The vote was agreed to

NOTES ON CURRENT TOPICS

Regency Bill Physicians and a Sovereign's Incapacity

In the House of Commons on Feb 4th, when the Regency Bill was considered in Committee, Mr **Logan** called the attention of the Home Secretary to the words (in Clause 2) " on the evidence of physicians or otherwise " In determining the mental condition of the monarch he took it that the duty would rest upon the evidence of physicians But the words " or otherwise " appeared to allow a latitude which was not intended in the Bill —Sir **John Simon** replied that the reason for the phrase was that while the main evidence in any such case would be that of skilled professional medical men, who had been attending the case, it would be true in any tribunal that wanted to gather information that the information would not be necessarily confined to physicians It might be nurses or other persons who had something in the way of information to contribute to the evidence to be considered It would be some comfort to Mr Logan to know that the Speaker of the House of Commons, the Lord Chief Justice of England, the Lord Chancellor, and the Master of the Rolls would be among those who would have to form this conclusion. He would be prepared, if it was the wish of the Committee, to exclude from the list of persons who had to make the declaration that the Sovereign was totally incapable the person who would become Regent, and who for the time being would act in the Sovereign's place One could conceive that a slightly invidious situation might otherwise arise —Mr **Ede** said the question was entirely medical The distinguished people mentioned in the clause had to be satisfied that the Sovereign was by reason of infirmity either of mind or body wholly incapable of performing his functions No one but medical people could properly express an opinion on that Those who had been associated with great mental institutions knew the great difficulty of a layman, no matter how distinguished, in dealing with mental cases As the clause was now framed there need be no evidence from a physician at all. There might be a case where people would be prepared to act without taking the evidence of physicians, or would ignore the evidence submitted by physicians There should be some provision in the Bill that physicians must at least give some evidence and that their evidence should be considered.—Sir **Archibald Sinclair** said that if the world came to the conclusion that he was mad he would be very sorry to have his case judged solely by specialised evidence He would much prefer to have it based on the opinion of ordinary common sense people who knew him well Where were the specialists to get their evidence ? A doctor by looking at a man could not discover if he was insane He had to get his evidence from someone, ' or otherwise " He had seen many reports of criminal cases in which eminent men with a great knowledge of mental disease had sworn diametrically opposite opinions

Clause 2 was ordered to stand part of the Bill and the Committee stage of the Bill was concluded

On consideration of the Bill on report, Mr **Logan** moved to leave out the words " or otherwise "—Mr **Ede** seconded the amendment He could not understand on what these distinguished people were going to act in deciding whether a person was physically or mentally incapable of discharging the functions of the Crown, unless it be medical evidence Could it be expected that these people would allow other evidence than medical evidence to outweigh the evidence submitted by distinguished alienists ?—Mr **Maxton** urged the Home Secretary to accept the amendment He agreed that it would not do to place their destinies as individuals merely in the hands of medical men. But the clause already met that point by having responsible experienced laymen to survey the expert medical opinion and decide whether it justified them in addition to their own knowledge as ordinary men in proposing that the King should not perform his functions, but that a Regent should be put in his place —Earl WINTERTON said he shared Mr Maxton s difficulty as to the wording of the clause as it stood —Sir J SIMON said he had not the slightest shadow of doubt that the words as drawn as far as he had any power to construe an Act of Parliament were perfectly appropriate to the case He was not prepared to contemplate the proposition that some unidentified successor of the Speaker in alliance with the Lord Chief Justice, the Lord Chancellor and the Master of the Rolls was in any conceivable circumstances going to arrive at a conclusion of this sort except upon material which four wise impartial people would accept He could conceive a case of obvious infirmity of body where they would not want elaborate expert evidence He was, however quite prepared that when the Bill reached the House of Lords there should be substituted some such words as these—

declare in writing that they are satisfied on evidence which shall include that of physicians He did not think it would make any material difference At the worst it would only mean that in some conceivable case which they hoped would never arise an eminent medical man would receive a fee for doing something which any honest human being could do

The amendment was by leave withdrawn and the Bill was read the third time

The Marriage Bill : New Medical Grounds for Nullity

EPILEPSY

On Feb 3rd the Marriage Bill was further considered by a standing committee of the House of Commons and Mr SPENS moved an amendment to delete the provision that nullity should be granted where a person was at the time of the marriage subject to recurrent fits of insanity or epilepsy Complete lunacy was already a ground for nullity and the question of mental deficiency was dealt with in another amendment Epilepsy often developed into some form of mental deficiency or insanity in which case it would be covered by the other provisions —Sir ARNOLD WILSON (speaking for the promoters) said these provisions were recommended as long ago as 1912 in both the majority and minority reports of the Royal Commission on the Marriage Laws The Commission reached the unanimous conclusion that recurrent fits of insanity or epilepsy should constitute a ground for nullity To the best of his knowledge the conclusion of the Commission had never been challenged On divorce yes but on nullity no The promoters only desired that this should be a ground of nullity where there was ignorance on the part of the other spouse of its existence at the time when the contract was made Epilepsy was normally hereditary and the consequences were disastrous Epileptics should be regarded as a class apart and be treated with the utmost humanity and sympathy, but they should not be regarded as fit members of society —The amendment was by leave withdrawn

MENTAL DEFECT

Sir A WILSON moved to delete the provision that nullity would apply when a state of mental unsoundness had become definite within six months of the marriage and to substitute the provision that nullity could apply where either party was at the time of the marriage or had been within twelve months of the marriage placed in an institution or under guardianship under Sections 3 6 8 or 9 of the Mental Deficiency Act 1913

Section 3 he said conferred power on the State to deal with defectives on the instance and on the initiative of parents. Under Section 6 it was possible to place defectives under guardianship upon petition after a full judicial inquiry before a court at which both sides had to be heard There were the most careful provisions against the consent of the parent or guardian being unreasonably withheld but it was provided that consent should not be deemed to be unreasonably withheld if withheld with the bona fide intention of benefiting the defective There was full provision for medical examination by two doctors and for a medical certificate Section 8 related to mental defectives who had been proved guilty of criminal offences, had been confined in an ordinary prison and were found on medical inquiry at the instance of justices to be mentally defective and were certified as such Section 9 the most important of all referred to persons found to be lunatics, often under the orders of the court and placed in a lunatic asylum, criminal or other and who were thereafter considered by doctors not to be insane but to be mentally defective

The borderline, said Sir A Wilson was narrow Alternatively there were men and women who had been confined in gaol for various offences against the State when the court had not had evidence before it that they were mentally defective but on examination, and after being watched, the conclusion was reached that they were mentally defective, and were certified under this Act If this amendment was inserted in the Bill it would be impossible for any persons to be the subject of a petition for nullity unless they had appeared before a court with full medical evidence as to their condition and unless they had had every opportunity of appearing or of having their own doctors.—The amendment was agreed to

VENEREAL DISEASE

Commander BOWER moved an amendment to leave out the paragraph providing that venereal disease should be a ground for nullity In the present state of medical knowledge opinion was he said, very much divided as to whether venereal disease was curable or not It was only within the last few years that great strides had been made in curing this type of disease and particularly in the case of hereditary disease. None of them could feel too strongly about the man or woman who would deliberately contract a marriage while suffering from such a disease But they must remember that venereal disease was often contracted innocently So long as a cure was probable or even possible, it was entirely wrong to allow a marriage to be dissolved when the person suffering from the disease might within a short period be again in perfect bodily health.—Sir A. WILSON said the promoters of the Bill intended at a later stage to define more closely venereal disease which had not yet been defined in any statute. They were endeavouring to produce a definition restricting it to those forms of the disease which were unquestionably perilous to the offspring as well as to the other spouse and which were also substantially not definitely curable but probably incurable as far as the recurrent possibilities of infection presented themselves He anticipated that it would be possible so to define the disease as to exclude those forms of venereal disease which were innocently contracted and which if properly treated, were seldom transmissible —The amendment was by leave withdrawn

Sir A. WILSON moved to leave out the words in a communicable form. If he said they properly defined venereal disease the words became unnecessary —The amendment was agreed to

On Feb 9th, before the Committee stage was concluded a new clause was added to the Bill providing that a person of unsound mind should be deemed under care and treatment while detained under the various Acts or as a criminal lunatic or while receiving treatment as a voluntary patient for a time following, without interval this period of detention and not otherwise

Medical Practitioners and Professional Secrecy

In the House of Commons on Friday Feb th Sir ERNEST GRAHAM LITTLE moved the second reading of the Medical Practitioners Communications (Privilege) Bill. He said that this was a Bill to provide that certain communications between medical practitioners and their patients should be privileged from disclosure The protection asked for had been rendered more necessary by certain circumstances which had arisen in the past 20 years and the difficulty really arose, or became accentuated, when the Royal Commission on Venereal Disease in 1916 demonstrated an incidence of that disease in our country so alarming that it became clear that very energetic measures were necessary to combat it The Local Government Board took up the recommendation and issued a very important series of regulations in 1916, which remained the operative measure in all hospitals and clinics in this country and the success that had followed had been very remarkable The Commission had stressed the importance of absolute secrecy if anything of a private nature was communicated to the doctor in charge of a case. The number of patients treated for these diseases to-day ran into astronomical figures, and that was the position which was being threatened by the present law Doctors and patients alike had regarded the rules as being a real protection, until two cases occurred in which medical men were called upon by the judge to give to a court certain information They objected, but they were told by the judges that they had no privilege and were obliged to reveal confidences made by the patient, even under those personal assurances The incidents aroused the interest of the medical profession and of the public, and the British Medical Association had vainly urged the Minister of Health at the time to see that his own regulations were carried out and to introduce legislation to prevent such an incident happening again The judge's ruling had, of course, conformed to the law of the country, but it was the medical view that the law required alteration

In 1927 Sir Ernest had introduced a Bill and on the advice of legal friends in Parliament had restricted its operation to venereal disease He had received support from medical, legal, and lay press and from eminent legal friends, who had welcomed the Bill as an opportunity of ventilating the subject The present Bill, without the restriction to venereal disease, had been "vetted" by one of our foremost judges, who had assured him that in his opinion its clauses were adequate to make its abuse highly improbable The principles embodied in it had also a very wide application to the treatment of maternal mortality, especially in the unmarried, and to cases under the National Health Insurance Act

The "professional secret," he went on, was absolute in almost all European countries, including France, Germany, Italy, Norway, and Switzerland, and its revelation was usually a criminal offence At an international conference in 1935 the resolution was unanimously passed "that the confidences of the patient to his doctor should be legally protected except in cases where professional secrecy would conceal crime or shield the criminal from proper punishment" It was improbable, therefore, that any serious disorders would result from the extension of the practice in this country which had been successful abroad He had been told by legal friends that if he restricted the operation of the present Bill to venereal diseases they would have less objection to it, but in that case the imputation would at once arise when the protection was pleaded in a court of law that the person pleading was, in fact, subject to venereal disease There was an increasing number of other cases, not venereal, in which it was equally urgent to get this protection, but if he could not induce the House to pass the Bill with the wider application he would be perfectly prepared to restrict it to venereal cases —Mr LOVAT-FRASER seconded the motion for the second reading

Mr DINGLE FOOT moved the rejection of the Bill He said that if it were confined to the question of venereal disease there might be something to be said for it Under the Bill a doctor must not give evidence of anything that he had discovered in the course of his treatment for the purpose of a cure, except in two very limited categories dealing with fraud and crime It appeared to him that the privilege might attach not to the patient, but to the doctor, who might be able to refuse, or might even be prevented from giving, evidence on his patient's behalf It would also make it exceedingly difficult for anyone to bring an action for negligence against a practitioner Either the doctor would be prohibited from giving evidence at all, or he could, in any case, refuse to give evidence He thought that as the Bill stood the consequences of its passing into law would be simply appalling

Mr ERNEST EVANS seconded the motion for rejection. He said the Bill was putting into the hands of the medical profession a privilege to which they were not entitled, and was imposing upon them a responsibility which very few of them would wish to have It might also involve considerable unfairness to the patient and interfere with the course of justice

Sir T O'CONNOR, Solicitor General, said he was afraid that he would have to recommend the House to refuse a second reading to the Bill The prime aim of the law was to secure justice, and it was very difficult to justify a privilege at all, for by its very nature it might involve doing injustice between man and man or between man and the State It had been held, however, that there were some cases where greater mischief would probably result from requiring the truth than from permitting the truth to be withheld, but these were very few Whose was the privilege? There was no definition in this Bill, but he was inclined to think that it was the doctor's There would be some remarkable consequences if this Bill, or anything like it, was passed. Indeed, he thought there was hardly any branch of the law, civil or criminal, in which the passage of this Bill in anything like its present form would not impede the administration of justice He was sorry that he could not hold out any hopes that any pruning or alteration of the Bill could make it a workable measure It was therefore one of those cases in which, with every sympathy for the intentions of the reformer, one could not help feeling that he was creating more anomalies than he was attempting to remedy

The motion for the rejection of the Bill was carried without a division.

Maternity Services in Scotland

In the House of Commons on Feb 4th, when the Maternity Services (Scotland) Bill was considered by a standing committee, Mr GUY moved an amendment that the authorities should arrange for domiciliary midwives to be supplied by such voluntary organisations as the Queen's Institute of District Nursing —Mr T M COOPER, Lord Advocate, said that fears that the subsection covering this point would be deleted were groundless, and the amendment was withdrawn.—An amendment moved by Mr PETHICK LAWRENCE that an anæsthetist should be available when recommended by the practitioner was agreed to —Mr LEONARD moved that consultations should only be with practitioners specially qualified in midwifery —Mr ELLIOT, Secretary of State for Scotland, said the selection of such a panel would be a very delicate matter, and on his suggestion the amendment was withdrawn.

Mr ELLIOT moved an amendment to ensure cooperation between the local authority and recognised medical schools and institutions for training midwives, this was agreed to

Sir ARCHIBALD SINCLAIR asked for the deletion of the subsection providing that fees for confinement should be paid to the local authority out of the woman's maternity benefits, with her authority Mr Elliot agreeing, the amendment was accepted

QUESTION TIME

MONDAY FEB 1st

Herbalists and Medical Practice

Sir Ernest Graham Little asked the Minister of Health whether in view of the claim that an Act (34 and 35 Henry VIII) dealing with herbalists gave to this section of unregistered practitioners the right to engage in medical practice without compliance with the Medical Act 1858 thus defeating the purpose of this Act to enable the public to distinguish between qualified and unqualified practice he would make provision to secure the repeal of this legislation of 400 years ago — Sir Kingsley Wood replied: I am advised that the Act of 34 and 35 Henry VIII enabled the persons named therein to treat certain medical conditions without incurring penalties under an earlier Act of the same reign which had given a monopoly of practice to physicians and surgeons approved thereunder by the Bishop and that it does not give to these persons the rights which are secured by registration under the Medical Act 1858 The latter Act however as the hon Member is aware does not prohibit practice by unregistered persons There appears therefore to be no conflict between the two Acts and I do not feel called on to take action in the direction suggested in the question

WEDNESDAY FEB 3RD

Black-coated Workers and Health Insurance

Mr Vyvyan Adams asked the Minister of Health when the promised scheme for the insurance of black-coated workers would be submitted to the House —Mr Hudson Parliamentary Secretary to the Ministry of Health replied: My right hon friend is not yet in a position to say when this Bill will be introduced but its preparation has now reached an advanced stage

THURSDAY FEB 4TH

Coroners and Alleged Press Persecution

Sir Assheton Pownall asked the Home Secretary whether he was aware of two further recent cases of persecution by members of the press; that in one case the coroner commented on a press photographer's disregard of the decencies of the case and in the other the coroner censured members of the press for behaving callously to a young girl whose fiancé had been found gassed and whether he would take further steps to compel the Newspaper Proprietors Association to stop the suffering caused by these intrusions by their representatives

Sir Percy Hurd asked the Home Secretary if his attention had been drawn to a case in the St Pancras coroner's court last Friday when it appeared that a journalist and a press photographer obtained admission to St Mary's Hospital Islington and the coroner commented on their scant regard for decencies in their treatment of a dying patient also to a case when the North Dorset coroner last week censured press representatives for having treated a young girl callously after the suicide of her fiancé in order to make a sensational story for their papers and whether seeing the recurrence of such cases the Government would give facilities for the passage of the Journalists (Registration) Bill now before the House whereby such conduct would come under disciplinary review by a body representative of all branches of the journalistic profession —Sir J Simon replied: I am in communication with the Newspaper Proprietors Association and the Newspaper Society on the whole subject and I am sending those bodies these further instances of complaint

Physical Training in Schools

Mr Gordon Macdonald asked the President of the Board of Education the number of physical training organisers in employment in the schools of England and Wales giving separate figures for Lancashire —Mr Oliver Stanley replied: There are 236 organisers of physical training in England and Wales, employed by 1 0 local education authorities In the geographical county of Lancashire there are 26 organisers employed by 17 local education authorities The county local education authority has recently appointed 2 organisers

Medical Inspection of School-children

Mr Day asked the President of the Board of Education what regulations were in force regarding the length of time local authorities should keep records of medical inspections of children during the time they were at school after they have left school and whether these were preserved or destroyed —Mr Oliver Stanley replied: The Board have issued no regulations on the subject but when asked for advice by local education authorities they have recommended that the records of medical inspection should be retained for about five years after the child leaves school and they understand that this is the usual practice for example in London the records are kept until the child's eighteenth birthday and in Birmingham for a period of five years

Sir F Fremantle Will provision be made for the use of these records by factory inspectors or other officers of the factory inspectorate?

No further answer was given.

Health Propaganda

Mr Rhys Davies asked the Minister of Health whether, in view of the fact that in America and other countries insurance companies spent large sums on health education he had examined the possibility of securing the coöperation of British insurance companies in the proposed national campaign for health education and physical training and whether he proposed to invite the insurance companies to contribute towards the cost of the national campaign.—Sir Kingsley Wood replied The general question of health education and propaganda is now under consideration but I understand that some work of this nature is already undertaken by insurance companies and I should certainly welcome its extension

MONDAY, FEB 8TH

Mr Bose's Condition

Mr Jagger asked the Under Secretary of State for India whether his attention had been drawn to the fact that Mr Subhas Bose was running a temperature and had recently lost 20 lb in weight and whether in view of the reported seriousness of Mr Bose's condition and public anxiety in India in this matter he would give instructions that Mr Bose be set at liberty and allowed the opportunity for proper medical attention either in India or abroad—Mr Butler replied: In view of his state *of health* Mr Bose was transferred in December from Kurseong to the Medical College Hospital Calcutta in order that he might receive medical treatment and I am confident that he has every facility there for obtaining proper attention

TUESDAY FEB 9TH

Cardroom Workers and Respiratory Illness

Mr Sutcliffe asked the Home Secretary whether he was now able to announce the constitution of the committee appointed to ascertain if a workable scheme could be devised for providing compensation for cardroom workers disabled by respiratory illness —Mr Geoffrey Lloyd Under Secretary Home Office replied My right hon friend much regrets the delay in constituting this committee but he can assure the hon Member that he is anxious to set it up as soon as practicable

Medical Practitioners and Treatment of Gas Cases

Mr Sandys asked the Home Secretary whether his department had drawn up a list of medical practitioners who had undergone an approved course of training in the treatment of gas cases; if so how many there were whether each had been allocated a prescribed district; and what arrangements had been made to mobilise their services in an emergency —Mr Geoffrey Lloyd replied Up to the end of January rather over 1500 medical practitioners had completed courses of anti gas training given by the 10 Home Office *medical instructors* originally appointed Six additional medical instructors are now at work As it is the aim to give this training to all medical practitioners in the country who are willing to receive it, there should be no need to allocate individual doctors to particular districts, but lists are available from which it would be possible at any time to notify to local authorities the names of those who had been trained in their respective areas

Mr SANDYS asked if the hon gentleman could say at what rate these practitioners were being trained, and whether all practitioners had been notified personally of the existence of this course

Mr LLOYD said that practitioners had not been notified at present, though arrangements were available locally for the purpose Doctors were being trained at the rate of 2000 a month

Health Insurance and Dental Treatment

Mr ROSTRON DUCKWORTH asked the Minister of Health whether he would submit to the appropriate authority the decision as to whether post dental surgical treatment should be a matter for the dentist or for the surgeon—Mr HUDSON, Parliamentary Secretary to the Ministry of Health, replied My right hon friend has no power to submit to any tribunal the general question raised by my hon friend The question whether any particular treatment is a service which a doctor can be called on to render under his insurance contract can be settled only on the facts of each individual case

PANEL AND CONTRACT PRACTICE

What is a Name?

No 7 of the medical certification rules gives instructions as to the particulars to be inserted in certificates issued to insured persons, these are to include the date of examination, the name of the patient, and a concise statement of the specific disease or bodily or mental disablement by which he is rendered incapable of work The practitioner must sign the certificate in his own hand and append the date on which he signs it, and must see that his name and address is stamped on the certificate The writing on the certificate must be in ink or other indelible substance All of which injunctions are simple and reasonable but they are not always followed Thus a practitioner recently pleaded the influenza epidemic as justification for writing certificates in ordinary lead pencil Another resented being asked to give something more than the surname of the insured person, and said that unless the approved society could satisfy him that any useful purpose would be served by the inclusion of initials he would continue merely to give surnames This point was settled some years ago, when the Minister of Health was asked to amend the rule so as to make it plain what constituted a name He was then advised that the surname alone is not the "name" of the patient within the meaning of the rule, and that in order to comply with the rule the christian name or initials of the patient must be inserted

Medical Mortgages Again

A firm of solicitors complained to an insurance committee that a practitioner had left his practice and "purported to transfer it" although he had mortgaged the practice to their clients, a firm of moneylenders, and had assigned his panel cheques to the mortgagees The committee replied that the practitioner had in fact retired from their medical list The solicitors then wrote that the reply did not meet the case, and proceeded "There is, as you know a definite mortgage, of which you are aware, and you have permitted something to happen to the prejudice thereof, and we should like to know what you propose to do in the matter You do not even indicate the name of the practitioner in whose favour Dr X has purported to retire" Needless to say the committee did nothing in the matter, and by this time the solicitor has probably learnt that the assignment of fees does not mean that the insurance committee need concern itself with anyone other than the practitioner so far as the insured patients are concerned.

Messages about Certificates

An insurance practitioner has had to appear before a medical service subcommittee because he listened to messages given by an insured person as having been sent by her approved society While the practitioner was on holiday his locum issued an intermediate certificate in mistake for a "first" The patient remained incapacitated and under treatment until a month later when she told the doctor that her society required a first certificate in respect of the earlier consultation He refused then, but a few days later she told him she had consulted the secretary of the society who had instructed her to ask again for a first certificate and for intermediate certificates covering the intervening period The doctor complied with what he regarded as the society's request, and subsequently the society referred his action to the insurance committee At the hearing the secretary said he would not request the issue of certificates other than in accordance with the regulations, but he volunteered the information that the patient in question finds it hard to understand English and he admitted having sent her back to the doctor to have the original certificate exchanged The committee had to find that the practitioner had committed a breach of the Terms of Service in antedating the certificates but they contented themselves with warning him of the necessity for the strict observance of the medical certification rules, while the complainant society will read with no particular satisfaction the sentence of the report which expresses the view that "clearly there could be no intention on the part of the practitioner to mislead the society, and it is perhaps unfortunate that messages should have been conveyed from the society to the practitioner by an insured person who, the society say, experiences difficulty in understanding English" Again and again practitioners have been warned that they should look with extreme suspicion upon messages which are alleged to have been sent by societies or their agents We need only mention the pregnant woman who has been told she is *entitled to sickness benefit and to get certificates* from her doctor

---

LONDON COUNTY COUNCIL HOSPITALS—The hospitals committee have reported to the London County Council the acceptance of tenders for hospital improvements costing over £125,000 These include the construction of a nurses' home at Hammersmith Hospital and the remodelling of the out patient department at St George in the East Hospital

GERMAN RADIOLOGICAL CONGRESS—The twenty eighth congress of the German Radiological Society will be held from April 12th to 14th at Breslau under the presidency of Prof Pleikart Stumpf The principal subject for discussion will be diagnostic and therapeutic technique its results and applications Further information may be had from Prof Karl Frik, Berlin, N W 87, Brückenallee 22

PUBLIC HEALTH

Influenza

THE figures for the toll of influenza in the week ending Feb 6th were not available when we went to press, but there can be little doubt that the graph had we been able to bring it up to date would now show a substantial drop for England and Wales following the earlier drop for London and the south eastern area It should soon be possible to construct a diagram illustrating the inexorable sweep of the epidemic from London west and north In the week ending Jan. 30th the great towns (outside London) with the highest death roll were Sheffield 65 Birmingham 56 Manchester 40 Leeds and Liverpool each 31 Warrington 28

A Maternity Scheme for Smethwick

Under the terms of the Midwives Act 1936 local authorities were required to submit proposals to the Ministry of Health for a scheme to come into operation on March 1st. In Smethwick (a county borough with 80 000 inhabitants) on the basis of last year's figures there should be about 700 confinements to be attended solely by midwives and 240 cases where a doctor will be in charge and the midwife present only as a maternity nurse. A scheme to provide domiciliary attendance on this basis was drawn up by Dr Hugh Paul the medical officer of health in September and was submitted in succession to the M. and C W committee the local doctors the midwives in the area, and was finally confirmed by the borough council on Jan 27th Accepting the Ministry s suggestion of 70 cases a year for a midwife or 30 for a maternity nurse the scheme proposes the appointment of seven municipal midwives with a senior midwife to exercise clinical supervision over them The town has been divided into eight districts in each of which one of these eight midwives is required to live. The eight places have been filled by applicants, 1 from London 3 from Smethwick and 4 from Birmingham They will receive a salary of £200 × £10–£250 with an allowance for uniform and travelling expenses. This is the same as the health visitors scale The senior inspecting midwife will receive £260 × £10–£300 One of the existing midwives has been required to surrender her certificate and will receive compensation on a five years purchase basis and one other has elected to surrender her certificate claiming three years compensation Antenatal and postnatal work will be done by the municipal midwives either in the patient s home or at the council s clinics where 90 per cent. of the expectant mothers already attend A graduated scale of fees has been drawn up based on gross family income five shillings being deducted for each child under 14. Attendance is free if the income is under 45*s* weekly and there is no maternity benefit the fee rises from £1 to a maximum of £2 10*s* where the income is over 65*s* These charges are about half those made for in patient treatment at St Chad s Hospital

MEDICAL NEWS

University of Cambridge

On Feb 5th the following degrees were conferred —

Ph.D —Inderjit Singh, M B
M B B Chir —J S Minett and A D D Broughton
M B —W H C M Hamilton
B Chir —O C Lloyd J S Ellis, and W S Nutt

At recent examinations the following candidates were successful :—

D M R E.

Part I —A P Booth, Jean Bouchard, A B Brereton J A Brocklebank, C. J O. Cooke, M W Dahab (with distinction) G G Doel, A M Evans T H T Gantly Muriel O Gibson, David Gold William Irwin, J L. King, Manuel Lederman C T MacCarthy, M A M Marel, J R. M Martin Ved Prakash Harold Pringle R R Rishi Aby Sirry C P Theron D C. Virmani, and J W Winchester

University of London

Mr H L Eason has been reappointed representative of the University on the General Medical Council

Applications for grants to assist original medical research from the Thomas Smythe Hughes and Beaverbrook funds should be made to the academic registrar between April 1st and May 15th A research studentship in physiology of the annual value of £100 will shortly be awarded Further information may be had from the academic registrar

Royal College of Physicians of Edinburgh

A quarterly meeting of the college was held on Feb 2nd with Dr W T Ritchie the president in the chair The following were elected to the fellowship : Dr Ernest T Roberts (Glasgow) Dr Eustace Russell (Brisbane) and Dr Douglas J Campbell (Southampton)

British Institute of Philosophy

An address will be given by Prof W G de Burgh entitled the Modern Gospel of Unreason on Tuesday Feb 16th at 8 15 P.M., at University College Gower street London, W C Application for tickets should be made to the director of studies at University Hall, 14 Gordon-square W C 1

Post graduate Course in Paris

A fortnight s course on vascular and renal diseases rheumatism and disorders of the endocrine system will be held at the Hôpital Necker Paris under the direction of Prof Maurice Villaret from March 8th to March 20th A further course on nutritional and digestive disorders will be held from April 10th to May 4th A visit to Vichy will be paid in connexion with the second course Further information may be had from the Laboratoire d Hydrologie et Climatologie thérapeutiques Faculty of Medicine Paris

Milbank Memorial Fund

Dr Frank G Boudreau has been appointed executive director of this Fund from April 1st in succession to the late Edgar Sydenstricker

A graduate in medicine of McGill University Dr Boudreau served in Europe during the late war and worked on meningitis among the troops on Salisbury Plain In 1925 he was appointed statistician-epidemiologist on the staff of the Health Organisation of the League of Nations and at present he is chief of the League s service of epidemiological intelligence and public health statistics.

St Andrews University

At a meeting of the general council particulars have been given of the chair of dental surgery which is to be instituted at the University The chair is to be in the faculty of medicine but the professor appointed will not be an examiner in the faculty ; otherwise he will be in the same position as the other professors The chair has been endowed by a gift of £17 500 and it is hoped that in addition a grant will be obtained from the Dental Board which will enable a full salary to be paid to the professor

The plans have been approved by the university court for the erection of an additional wing to form an extension of St Salvator s Residents Hall for men students in St Andrews at an estimated cost of £40 000 Grants have also been made for alterations to the students union at Dundee the library buildings of University College Dundee and the residence for women students in Airlie place Dundee

St George's Hospital

At the annual meeting of the ladies association of this hospital it was announced that, as a result of entertainments organised by the association last year, over £12,000 has been collected for the rebuilding fund

A Course in Orthopædic Surgery

A post-graduate course in orthopædic surgery will be held at the Royal National Orthopædic Hospital 234, Great Portland street, London, W, from March 8th to 20th Those taking part may attend operating sessions and the practice of the hospital Application should be made to the secretary

Royal Microscopical Society

On Wednesday, Feb 17th, at 5 30 P M, Dr J A Murray, F R S will address a meeting of this society to be held at B M A House, Tavistock square, London, W C He will speak on a method for paraffin sections of insect and other chitinous material

Lectures on Pacifism

On Feb 15th, Feb 22nd, March 1st, and March 8th, at 8 P M at the Conway Hall, Red Lion square, London, W C, Dr Graham Howe will give four lectures on pacifism Their titles are anxiety, aggressiveness, guilt, and wisdom Lord Allen of Hurtwood will take the chair at the first lecture Tickets may be had from 99, Clare court, Judd street, W C 1, or at the door

Lectures in Hospital Administration

A three months' course of lectures and demonstrations on clinical practice and hospital administration will be given by Dr J V Armstrong at the Brook Hospital, Shooters Hill, Woolwich, S E, on Mondays, Wednesdays, and alternate Saturdays, beginning on Monday, April 5th Further particulars may be had from the medical officer of health of the London County Council, Public Health Department (Specials Hospitals) County Hall, S E 1

Friern Hospital for Nervous and Mental Disorders

On Feb 5th Mr Herbert Morrison, leader of the London County Council, opened the new nurses' home at this hospital, which was formerly known as Colney Hatch Hospital As far as possible the home has been planned to avoid overlooking the hospital buildings It has four storeys and contains a dining room which will seat 100 nurses, a kitchen, sitting rooms, and a "quiet room" Sleeping accommodation is provided for 117 nurses Till now most of the nurses have been living in scattered quarters throughout the hospital Mr Morrison pointed out that modern treatment insists more and more on helping the individual patient and less and less on restraint and the sinking of the individual in the mass This new attitude threw more work and imposed a greater strain on the nursing staff who have the right to expect to be housed in a reasonable degree of comfort in the hospital in which they work and which is also their home The total cost of the building and its equipment is £23,500

Edinburgh Medical Missionary Society

At the annual meeting of the Edinburgh Medical Missionary Society on Jan. 28th, the president, Dr R A Fleming made a strong appeal for increased financial support The work of this society consists in assisting financially in the medical education of men and women who wish to devote themselves to medical missionary work in connexion with any of the Protestant Churches, and also in maintaining two hospitals overseas, as well as the well known Livingstone Dispensary in the Cowgate, where the students of the Society receive their training in dispensary and mission work and from which important medical work is done in one of the poorest districts in Edinburgh The annual report shows that the income last year fell short of expenditure by £3000 The costs had increased both in their hospitals abroad and in their work in Edinburgh The health authorities wanted them to assist in the medical work of the new housing area at Niddrie to which some of their Cowgate patients had been moved but in view of the deficit the Society could not undertake this fresh financial responsibility unless the authorities offered definite financial aid and the matter was therefore at present in abeyance

British Empire Cancer Campaign

The Duke of Gloucester has consented to become the president of this body

Scunthorpe War Memorial Hospital

This hospital, which was opened seven years ago, must now find £25,000 for extension as well as a considerable sum for maintenance

Rotherham Hospital

This hospital of 130 beds has to raise £12,000 for improvements and alterations It was built in 1873 when it had only 25 beds

Hospital Cooperation at Liverpool

The Liverpool city council has approved of the establishment of a Liverpool hospitals joint committee which is to be a permanent body securing coöperation between voluntary and municipal hospitals

Yateley and District Hospital

An extension to this hospital has been opened, consisting of a new ward, operating theatre, X ray department, and accommodation for the staff

Leeds Women's Hospital

A new ward, costing £7000, and an operating theatre were opened at this hospital on Feb 1st In order to pay for the extensions the hospital has had to incur a bank overdraft An additional annual outlay of £2000 will also have to be found for maintenance

Night Motor Service on Merseyside

The hospital night volunteer motor service of this district, which held it annual meeting recently, has in five years answered over 2000 night calls to take relatives to the beds of seriously ill people or to bring blood donors to the hospitals from their homes

MONDAY Feb 15th —1 P.M, Prof G E Gask: John Hunter in the Campaign in Portugal 1762–63

BRITISH POSTGRADUATE MEDICAL SCHOOL Ducane road W
MONDAY Feb 15th —2 30 P.M Dr H MacLean Nephritis and Allied Conditions
TUESDAY —2 P.M Dr Janet Vaughan Pregnancy Diagnosis
WEDNESDAY —Noon clinical and pathological conference (medical) 2 30 P.M., clinical and pathological conference (surgical). 4 30 P.M., Mr A S Parkes F R.S Experimental Endocrinology
THURSDAY —Noon, clinical and pathological conference (obstetrics and gynæcology) 2.30 P.M, Dr Duncan White Radiological Demonstration 3.30 P.M Mr A K Henry Demonstrations on the Cadaver of Surgical Exposures. 3 30 P.M Prof E C Dodds The Female Sex Hormones
FRIDAY —2 P.M operative obstetrics 2 30 P.M, Prof Hey Groves Fractures. 3 P.M department of gynæcology pathological demonstration
Daily 10 A.M to 1 P.M medical clinics surgical clinics and operations obstetrical and gynæcological clinics or operation

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE Hammersmith, W
MONDAY, Feb 15th —10 A.M skin clinic. 11 A.M., surgical wards P.M., surgical and gynæcological wards eye and gynæcological clinics.
TUESDAY —10 A.M medical wards 11 A.M surgical ward 2 P.M throat clinic 4 15 P.M. Dr Maurice Shaw The Hollow Viscera and their Symptoms
WEDNESDAY —10 A.M children s wards and clinic 11 A.M medical wards 2 P.M, eye clinic gynæcological operations. 4 15 P.M Mr Steadman: Pyorrhœa Alveolaris
THURSDAY —10 A.M neurological and gynæcological clinics Noon fracture clinic P.M eye and genito-urinary clinics 4 15 P.M Mr Sangster Simmonds: Diseases of the Alimentary Tract
FRIDAY —10 A.M medical wards skin clinic Noon lecture on treatment P.M throat clinic. 4 15 P.M., Dr Sydney Owen: Meningitis
SATURDAY —Children s and surgical clinics 11 A.M medical ward
The lectures at 4 15 P.M are open to all medical practitioners without fee
Daily 2 P.M, operations medical and surgical clinics

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION 1 Wimpole-street W
MONDAY Feb. 15th to SATURDAY, Feb 20th —ST JOHN'S HOSPITAL, Leicester-square W C. afternoon course in dermatology (open to non members) —NATIONAL TEMPERANCE HOSPITAL, Hampstead road N W, Tues 8 30 P.M Mr A Dickson Wright: Neck Thurs., 8 30 P.M Mr R J McNeill Love: Skull and Brain —CHELSEA HOSPITAL FOR WOMEN, Arthur-street S W all-day course in gynæcology —NATIONAL TEMPERANCE HOSPITAL, Hampstead road N W, Tues and Thurs 8 P.M M R C P clinical and pathological course —PRINCESS ELIZABETH OF YORK HOSPITAL, Shadwell, E., Sat and Sun., course in children s diseases —Courses are open only to members of the Fellowship

LONDON SCHOOL OF DERMATOLOGY 5 Lisle-street W C.
TUESDAY Feb 16th —5 P.M Dr H Corsi Diseases of the Nails
WEDNESDAY —5 P.M, Dr I Muende Histopathology of Some Common Skin Diseases

HOSPITAL FOR SICK CHILDREN Great Ormond-street W C.
THURSDAY Feb 18th — P.M., Mr Denis Browne Pregnyl or Operation for Undescended Testis? 3 P.M Dr Wilfrid Sheldon The Treatment of Rheumatic Conditions.
Out patient clinics daily at 10 A.M and ward visits at 2 P.M

NATIONAL HOSPITAL Queen-square W C
MONDAY Feb 15th —3.30 P.M. Dr Symonds Cerebral Tumours (III)
TUESDAY —3.30 P.M Dr Carmichael Polyneuritis
WEDNESDAY —3.30 P.M., Dr Kinnier Wilson Clinical Demonstration
THURSDAY —3.30 P.M Dr Carmichael Subacute Combined Degeneration of the Cord
FRIDAY —3.30 P.M Dr Denny Brown The Motor Cortex
Out patient clinic daily at 2 P.M.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART Westmoreland-street, W
TUESDAY Feb 16th —5 30 P.M., Dr John Parkinson Radiology of the Aorta

CENTRAL LONDON THROAT NOSE AND EAR HOSPITAL Gray's Inn road W C
FRIDAY, Feb 19th —4 P.M Mr C Gill-Carey Simple and Malignant Growths of the Larynx.

HAMPSTEAD GENERAL AND NORTH WEST LONDON HOSPITAL N W
WEDNESDAY Feb 17th —4 P.M Dr H M Oddy: The Significance of Cough in Children

ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE, Ranelagh road S W
FRIDAY Feb 19th —4.30 P.M., Dr Albert Eidinow The Technique of Treatment by Local and General Ultraviolet Irradiation of the Skin in the Rheumatic Diseases

SOUTH WEST LONDON POST-GRADUATE ASSOCIATION St. James Hospital, Ouseley road S W
WEDNESDAY Feb 17th —4 P.M Mr Rainsford Mowlem: Some Common Cases Treated by Plastic Surgery

LEEDS GENERAL INFIRMARY
TUESDAY Feb 16th —3 30 P.M Mr A. Gough Diagnosis of Pregnancy

ANCOATS HOSPITAL Manchester
THURSDAY Feb 18th —4 15 P.M, Dr Langley Diagnosis and Treatment of Diabetic Coma

ST MARY'S HOSPITALS Manchester
THURSDAY Feb 18th (Whitworth-street West Hospital) 4 15 P.M Dr R. Newton Breech Delivery (With film)

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION
WEDNESDAY Feb 1 th —4 15 P.M (Western Infirmary) Dr Allison D McLachlan: Seborrhœic Dermatitis

Appointments

CARSE, JOSHUA, M D Durh., D.P.M has been appointed Assistant Hon Physician in charge of Out patient Clinic for the Treatment of Early Mental Diseases at the Northampton General Hospital

DOBBS R H., M B Camb M R.C.P Lond., Hon Assistant Physician to the Princess Louise Kensington Hospital for Children

FRANKLIN A W M B Camb, M.R.C.P Lond Assistant to the Pædiatrician and Medical Officer to the Infant Consultation Centre at Queen Charlotte s Maternity Hospital

HAWKSLEY, J C M D M R C P Lond Hon Physician to St. Peter's Hospital, London

HENNELLY, T J., M D N U I D P.M Medical Superintendent Cardiff City Mental Hospital

HUTTON, H G, B.A Camb., M R.C.S Eng., Assistant School Medical Officer for Leeds

McGOURTY H D M B Dub., D.P H Assistant Tuberculosis Officer at Winter street Hospital Sheffield

MACNAB, G H M.B Edin., F R.C.S Eng Assistant Surgeon to the Westminster Hospital

ORLEBAR Doris M M.A. Oxon., M R C S Eng D P.M Hon Psychotherapist to the Out patient Department of the West End Hospital for Nervous Diseases, London

PEARCE J D W M D M R C P Edin D P.M., Hon. Psychotherapist to the Out patient Department of the West End Hospital for Nervous Diseases, London

RATNER, EDWIN M D Manch, D P H Consultant Tuberculosis Officer to the West Riding County Council

ROBERTS G J., M D Edin, D P H, Assistant Medical Officer of Health and Assistant School Medical Officer for Bootle

ROWLEY, G D M B Edin, Senior Resident Medical Officer at the Hospital for Sick Children, Newcastle-upon Tyne

SHUCKSMITH H S M B., F R C S Eng Resident Surgical Officer at the General Infirmary Leeds

TILL, A S F R C S Eng., Surgical Registrar at the Middlesex Hospital

VAUGHAN JACKSON O J, B M Oxon., F R.C S Eng Surgical First Assistant and Registrar at the London Hospital

Certifying Surgeon under the Factory and Workshop Act
Dr H O Mount Jones (Llangollen District, Denbigh); Dr W L Anderson (Dunbar District East Lothian)

Vacancies

NOTES, COMMENTS, AND ABSTRACTS

THE INTESTINAL FLORA AND ITS RÔLE IN THE LIFE OF MAN AND THE HIGHER ANIMALS *

By P Kouchakoff
OF THE INSTITUT DE CHIMIE CLINIQUE LAUSANNE

The rôle and significance of the intestinal flora in the processes of digestion have not yet been sufficiently elucidated. As is known there are two groups of microbes microbes of fermentation and microbes of putrefaction In new born animals the intestine is always sterile the microbes making their appearance during the first hours of life In the tropical fruit bats known as flying foxes the alimentary tract is almost sterile My own observations in the north polar regions conducted in the course of six years in Northern Siberia Nova Zembla and in Franz Josef Land have shown that the intestine of polar bears contains only one kind of microbe —*Bacillus coli*—belonging to the fermentative group (over 100 observations) whereas in sea gulls and migratory birds I found a considerable and varied intestinal flora. On the other hand in the local polar birds the flora became progressively poorer as one approached the North Pole For example in the genus uria (auks) the intestine was found to be perfectly sterile (more than 300 observations)

Thus in some animals the entire process of digestion and assimilation is purely physiological, without any intervention on the part of the microbes It is also well known that all experiments on feeding new born animals with sterile food and in sterile surroundings rapidly leads to their death. My own experiments with new born polar bear cubs kept together with dogs demonstrated that these animals are not immune against the putrefactive microbes and that invasion of the intestine by microbes of this group makes them ill and sometimes kills them (three out of eight died). Uninterrupted observations in the course of two years demonstrated that in bear cubs fed on a human diet and having an abundant intestinal flora growth and general development were retarded as compared with wild cubs of the same age, although the animals lived in complete freedom under identical polar conditions

It will be noted that the facts mentioned above are contradictory since on the one hand under existing conditions of nutrition the absence of an intestinal flora is fatal to the animal while on the other hand the appearance of an abundant intestinal flora likewise causes their death.

It has been proved that between the two groups of microbes—the fermentative and the putrefactive—there is a constant antagonism and that the saprophytic intestinal microbes may in certain cases become pathogenic and not only cause diseases in various organs but bring about different kinds of septicæmia

If the intestinal flora is necessary for the *proper* nutrition of the animal and for the assimilation of the food it is difficult to understand the existence in the general harmony of the organism of this antagonism between the different species of microbes It is equally incomprehensible that these microbes while breaking up the foodstuffs biologically produce by means of their by products intoxication of the organism which they are supposed to assist. In a series of investigations I have shown that the solution of these questions lies in the proper nutrition of the body

Virchow's recognition of alimentary leucocytosis —the name given by him to the increase in the number of leucocytes occurring after each meal—as a physiological phenomenon represents one of the greatest scientific errors as the result of which the works of all subsequent investigators were based on false premises My own experiments have shown that alimentary leucocytosis does not take place after consumption of food in the form in which it was produced in nature but that leucocytosis occurs after consumption of food altered by high temperatures and by complicated manufacture The alimentary leucocytosis is an indication of some pathological process taking place in the organism as the result of the introduction of food which is not readily assimilable. If the altered natural products of our usual diet are combined with small amounts of raw products the leucocyte formula of the blood can be maintained at its normal physiological level and I have succeeded in determining the necessary *proportions.*†

In order to determine the true significance of the intestinal flora and of its rôle in the digestive processes further experiments should be conducted on animals and human beings fed on a diet which causes no changes in the leucocyte formula of the blood but maintains it on the same physiological level.

INCIDENCE OF SYPHILIS A CORRECTION

In a leading article on Jan. 2nd we referred to the report of a New York commission appointed to study methods of control of venereal disease in the Scandinavian countries and in Great Britain. The figures studied and recorded in this report showed evidence of decline in the incidence of syphilis in all the countries concerned; and it was noted that in 1933 the reported cases reached the low level of 7 per 100 000 in Sweden 20 in Denmark, and 30 in Oslo the chief city of Norway We compared these figures with the number of new cases of syphilis reported as having attended treatment centres in this country during that year, amounting to 21 525 —an incidence of 56 per 100,000 in a population of 38 000 000 It seems that there was no real basis for comparison between these sets of figures, since the Scandinavian reports referred *to fresh cases* of early syphilis attending for treatment for the first time whereas our figure of 21,525 included cases of old-standing syphilis as well as recent infections and also a certain number of duplicates—that is to say patients who were transferred from centre to centre and were recorded as new cases at both Another source of error was the fact that the population of England and Wales during 1933 exceeded 40 000 000 The number of cases in which the infection was of less than one year's duration amounted to 8000 and it is this figure which is most nearly comparable with the figures for the Scandinavian countries. By this standard the incidence is approximately 20 cases per 100 000 in a population of 40 000 000 and the comparison makes it clear that methods of control here are more effective than we indicated Nevertheless, it must be remembered that the figures from treatment centres in this country give only a propor tion of the total incidence of the disease, since there is no system of compulsory notification as in Scandinavia, where—in Sweden and Denmark at all events—it is believed that the reporting of cases is faithfully carried out by practitioners It is interesting to note that the annual report of the chief medical officer of the Ministry of Health for 1935 records a still further decline in the incidence of syphilis in this country, the total cases falling to 19,335, of which 5971 were regarded as fresh infections This is the lowest figure yet recorded An instructive map reproduced opposite p 94 of the chief medical officer's report shows increases or decreases for the various counties

* Summary of a paper read before the International Congress of Microbiology London 1936

† See the proceedings of the first International Congress of Microbiology in Paris 1930 and of the International Physiological Congress in Rome 193[illegible]

PROF YAS KUNO

HOWEVER important his researches and however valuable his contribution to the welfare of humanity in general, no one experiences the fullest satisfaction with his work unless he has stimulated some of those around him to follow in his footsteps The history of medicine abounds with examples of men who have gathered round them a group of younger workers and filled them not only with their own enthusiasm but with an intense and often touching loyalty In 1934 Prof Yas Kuno of the Manchuria Medical College, Mukden, published in book form an account of the physiology of human perspiration, the most complete account in existence and yet little more than a record of the researches of his own school into this neglected subject Now on his retirement from the chair he has held for 25 years his former pupils have demonstrated their affection and regard in a way that any teacher would be proud of The whole of the December number of the *Journal of Oriental Medicine* is taken up by their writings, dedicated to him "in humble recognition of his devoted guidance" We congratulate Prof Kuno not only on his own contributions to medical science but on the happy relations he has enjoyed with his disciples, as they call themselves With them, we hope that he may long be spared to 'devote his life to the benefit of the medical world and of humanity at large," and it is good to know that he will have a new laboratory in which to pursue these ends

THE FATE OF THE SPLENECTOMISED

DOES a man surgically deprived of his spleen live happy ever after? Is he more blessed or less so than his neighbour still in possession of that somewhat mysterious organ? Erik Ask-Upmark of Lund has collected 94 cases from writings on the subject and has also followed up 100 cases of splenectomy done in Sweden (*Acta med scand* Suppl lxxviii, p 226) A small control group of 10 cases was examined at the Medical Clinic at Lund but the remaining 90 were investigated by means of a questionnaire sent through the post More than half the patients were under 21 and the average post-operative period at the time of observation was 8 years About half the patients reported that they had had good health since the operation the remainder having suffered from various disorders the most important of which was tuberculosis Although the morbidity-rate was not striking the mortality-rate from tuberculosis in these patients was high both in the cases followed up and in the cases collected from the writings—a result which supports the view that the spleen may exert a *protective function against tuberculosis* The incidence of appendicitis also seemed higher than might have been expected Lassitude was a symptom commonly observed at any rate in the first year after operation, and sometimes it persisted indefinitely, in some cases also remarkable alterations in body weight both in an upward and downward direction, were noted Ask-Upmark concludes that allowing not less than a year for his body to accustom itself to the loss of the spleen a splenectomised person should be regarded as at least a fairly good insurance risk.

NEW PREPARATIONS

TANNOL is an emulsion of acriflavine in paraffin with 10 per cent of tannic acid Acriflavine emulsion has been strongly recommended as a first-aid antiseptic dressing for burns and scalds, and the intention here is to combine its virtues with those of tannic acid. The Tannol is to be applied on lint under a light bandage, and the dressing may be renewed if necessary twice a day It is made by Clay and Abraham Ltd of Liverpool

TESTOVIRON is the name under which Schering Ltd (185, High Holborn, London, W C 1) issue their crystalline preparation of testosterone propionate Testosterone is the testicular hormone, and the propionic acid ester is the most active compound of it so far available Clinical experience with it is scanty, but the manufacturers believe it to be useful at the male climacteric, in conditions of sexual deficiency (e g, hypogonadism and some types of sterility), in cases of early prostatic hypertrophy, and for various other disorders

ANTIHÆSIN is described as "a non irritant, non inflammable solution for the painless removal of plaster strapping" A little of it is insinuated between plaster and skin, or the whole surface may be soaked if need be, after which the plaster strapping can be removed smoothly and evenly It is manufactured in England by Allen and Hanburys, Ltd, London, E 2

SYRUP AMMONII MANDELAT—Mandelic acid is bactericidal only in an acid medium, and when sodium mandelate is used against urinary infections ammonium chloride is given at the same time to ensure acidity of the urine If ammonium mandelate is employed the addition of ammonium chloride is usually unnecessary, and C J Hewlett and Son Ltd (35, Charlotte-street, E C 2) put forward their new syrup as a convenient and pleasant means of carrying out mandelic acid therapy Two teaspoonfuls contain 3 0 grammes of the acid

STREPTOCIDE—On Dec 5th last we mentioned that Evans Sons Lescher and Webb Ltd were issuing *p* aminobenzenesulphonamide to practitioners, free of charge Their preparation of this substance is now on the market under the name of Streptocide

"TABLOID" BRAND SULPHONAMIDE P is the shorter name by which Burroughs Wellcome and Co (Snow hill Buildings, E C 1) now describe *p*-aminobenzenesulphonamide They suggest that intramuscular injection may be tried when it cannot be given by mouth, and they offer suggestions for preparing a suitable solution

---

The GLAXO LABORATORIES LTD (Greenford, Middlesex) have produced "The Ostermilk Book" on the care of mother and baby It is in three parts (Before Baby Comes The First Year and the Toddler) and it contains useful information and sensible advice in simple form Naturally enough, the supplementary foods and preparations recommended are those of the Glaxo firm

From CADBURY BROS, LTD, of Bournville, comes "The Cacao Tree," which describes their products in terms of medical practice It begins with an apocryphal old song "The Milk, the Malt, and the Chocolate Tree, the more you eat 'em the better you be," and it ends with reasons for acting on this advice by taking Bourn-vita Emphasis is laid throughout on the advantages of chocolate beverages for people who are nervous or irritable, as alternatives to those containing caffeine

---

AN UNUSUAL STRIKE—The current issue of the *Münchener Medizinische Wochenschrift* relates on the authority of Reuter a strike for higher wages in a big London hospital Out of sympathy for the strikers all the 850 patients in the hospital refused food and medicine and the management was obliged to make terms with the strikers The hospital is not named

ADDRESSES AND ORIGINAL ARTICLES

RITUAL PURGATION IN MODERN MEDICINE *

By L J Witts M.D Manch F R C P Lond

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON AND DIRECTOR OF MEDICAL UNIT ST BARTHOLOMEW'S HOSPITAL

> I would not have you take too much Phisick, for it doth all waies make me worse and I think it will do the like with you "
>
> Charles II

Purgation like emesis fasting bleeding and other methods of depletion has been used from the dawn of history in the effort to relieve physical illness and mental distress Purgation calendars indicating the times and constellations when these offices should be performed were the first printed documents of medicine Much of the purging carried out by medical men to-day is rooted in archaic and primitive beliefs rather than physiology and pathology There are profound sources for these beliefs with which a cursory study of Freudian psychology will acquaint you. Suffice it to say that the pleasure felt by the infant in the discharge of bodily functions and the pain caused by the need to discipline them play an important part in the mental development of mankind Little children are told that they are good when they evacuate to order and the idea that an action of the bowels is something meritorious and certain of reward lingers in many adult minds You may phrase these beliefs anew and speak of increasing the excretions flushing out toxins, or preventing auto intoxication but whenever you are tempted to purge a patient who has a fever or who is to face the ordeal of a surgical operation I ask you to pause and consider whether you are not exchanging the laboratory jacket of the twentieth century for the panoply of the witch doctor and the exorciser

As recently as 1918 Lane attributed to intestinal stasis loss of the feminine contours, low blood pressure high blood pressure asthma, neuritis depression melancholia mastitis cancer tuberculosis, rheumatism goitre flat feet foul breath offensive perspiration and discoloration of the skin All these maladies were to be prevented or relieved by the more frequent action of the bowel Was there ever a more fantastic statement of the rewards of being good ? Later focal sepsis replaced constipation as the bogy and organs such as teeth tonsils appendix, gall bladder uterus, and prostate were sacrificed on the altar of health The excesses committed in the elimination of intestinal toxæmia and focal sepsis show that ideas derived from religion and magic are still at work in Western medicine and that men are still ready to put their trust in purification and blood sacrifices in their time of trouble My purpose in this lecture is to suggest that much of the purgation of sick people carried on to-day is harmful and only to be explained by thoughtless adherence to tradition The evil effects of constipation have been exaggerated few if any of the] symptoms of acute illnesses can be attributed to constipation or relieved by emptying the bowel and many of them are much aggravated by purgation

Bowel Physiology

In certain people especially patients interest in the products of the large intestine can only be described as morbid and excessive Students and many doctors on the other hand, are too ready to accept at their face value the noughts and crosses which the nursing staff inscribe on the temperature charts, without realising that a cross may mean anything from a little damp flatus to the voluminous evacuation of sprue If our attitude to the action of the bowels is to be rational, we must observe the number size and consistency of the stools the state of the rectum, the method of administration and the volume of enemata and the dosage and effect of purgative drugs with the same care as every other detail of investigation and treatment and not delegate these matters to the nursing staff In health the bowels are opened once or twice a day according to diet and habit This rhythm is easily disturbed in sickness not always unavoidably Too often patients in hospital are kept in bed because there is inadequate accommodation for them to be up rather than because their disease requires it Whenever possible the doctor should encourage them to get up for breakfast and the toilet instead of inhibiting the delicately conditioned reflex of defæcation by a bed pan If a patient misses a daily action in his new surroundings it is important to avoid a panic flight to purgatives which will injure the normal rhythm much more than a single day's omission. Some patients undoubtedly are helped by a mild aperient but one should stop the practice prevalent in many wards in which a Borgia like sister makes an evening round and administers a powerful cathartic to any patient who is considered not to have done his duty If a patient is too ill to get up to use the toilet, then he is possibly too ill to tolerate a purgative and every such patient should be considered as an individual and not submitted to routine purgation.

A formed stool consists of unabsorbed food debris and the bodies of dead bacteria The longer it is retained in the distal colon the more inert it becomes Aperients, by hurrying undigested residues through the proximal colon and making them more watery increase the number of viable bacteria in the stool. It is an old observation that relapses can be provoked in *Bacillus coli* pyelitis by giving an aperient Apart from mechanical distension a constipated stool exerts little more influence on the patient in the colon than in the bed pan The ill effects of constipation, as of masturbation are almost entirely psychogenic and due to worry over disturbance of habit. Boys with megacolon and prolonged retention of fæces show little evidence of toxæmia As I shall indicate later I have deliberately kept ill people constipated for a week or longer without any symptoms from the bowel Some inspissation of fæces may occur especially in old people with the formation of a rectal plug which requires assistance in dislodgement but that is the only difficulty The small intestine empties itself as completely as possible 14 hours after food and no purgative can make it any cleaner The whole of the large intestine is accessible to lavage from the rectum There is rarely any urgency for the bowels to be opened in acute illnesses and when an action becomes desirable it should be secured by enemata and not by drugs

Ill Effects of Purgation

Is there any harm in purgation ? In patients who are acutely ill it may be a most dangerous expedient Physiology has long emphasised the importance of a constant internal environment for the organism, but it is only in recent years that medicine has realised the profound effect which increase in the secretions and excretions may have on that inner environment A man may go without food for many days, but the deprivation of water or loss of the soluble salts of the organism is badly borne The osmotic equilibrium between the cells and the body fluids is disturbed, the volume of blood is diminished, the circulation collapses, the renal function is impaired, the acid-base metabolism undergoes fluctuations which are beyond the bounds of compensation

---

* An address given to the Manchester Medical Students Society on Jan 29th 1937

The output of water is normally concerned with the excretion of waste materials in solution by the kidney and in semi solid form by the bowel, and the dissipation of body heat by vaporisation from the skin and lungs Excretion of water by the kidneys and the bowel may be greatly curtailed in emergency, and this is the chief reason for the concentrated urine and the constipation of fever Vaporisation by the skin must continue as long as life is to be maintained and, when the temperature is raised, several litres a day may be lost in this way Coller (1936) has calculated that by the time a patient begins to show signs of dehydration, such as a dry hot skin, a dry tongue, sunken eyes, fever, and a low output of urine, there is a fluid deficit equal to about 6 per cent of the body weight or nearly four litres in the average adult The obvious need in such a case is to increase the fluid intake, by parenteral channels if necessary, until the signs of dehydration disappear and the urine volumes return to normal. In acute illnesses constipation is usually a symptom of dehydration, and to purge a dehydrated patient, depleting the fluid reserves still further, is always foolish and often disastrous Here are some examples from my own experience —

In Addison's disease the water balance is very unstable, owing probably to the loss of the suprarenal control of the excretion of sodium salts by the kidney Mrs A, aged 43, had been under treatment for Addison's disease for nine months As I wished to study her metabolism further, her Cortin was stopped for a few days on Nov 23rd, though salt by mouth was continued In order to obtain a good sample of fæces for analysis, the house physician gave her senna infusion on the evening of the 28th and again on the morning of the 29th Five stools were passed on the 29th and her temperature rose abruptly On the 30th it reached 106° F and she was semi conscious with rigid limbs She was terribly ill for over a week, but we gave her saline infusions and cortin in doses of 100 c cm daily and she eventually recovered I interpreted her illness as a crisis of suprarenal insufficiency with dehydration fever and muscle cramps provoked by a very moderate catharsis

A man of 52 who had had symptoms of duodenal ulcer since 1929 developed pyloric stenosis at the beginning of 1936 He had suffered from copious and projectile vomiting for two months before admission to the medical unit, and had been performing gastric lavage for one month His general condition appeared satisfactory, blood pressure 105/110, blood count normal blood urea 47 mg per 100 c.cm , alkali reserve 62 vols carbon dioxide per cent , plasma chlorides 577 mg per 100 c cm While, however, his best weight was 10 st 10 lb , his present weight was only 8 st 2 lb After further gastric lavage he was *transferred to the surgical unit for gastro-enterostomy* on the fifth day The operation went very smoothly, but on the fourth day after the operation, following an aperient, his bowels were opened four times On the fifth day his bowels were opened nine times and his general condition deteriorated rapidly The blood volume was diminished, as shown by the fact that the red cell count had risen to 6 8 millions per c mm The blood urea was 320 mg per 100 c cm Next morning the patient rather suddenly collapsed and became dyspnœic his extremities were blue and cold, his face shrunken, and his systolic blood pressure was below 60 mm Hg The blood urea had risen to 440 mg per 100 c cm , the plasma chlorides had fallen to 483 mg and the alkali reserve to 28 volumes per cent Efforts to restore the circulation were of no avail and the patient died a few hours later Although this man's blood count and blood chemistry were normal, his loss of approximately 25 per cent of his weight was associated with such a great diminution in the fluid and mineral reserves of the body that he was unable to cope with a moderate diarrhœa, and quickly succumbed to uræmia and acidosis

A man of 43 with bronchiectasis of the left lower lobe developed a massive pneumonia with high fever, which necessitated treatment in the oxygen tent from the 3rd to the 14th day His illness was punctuated by two attacks of diarrhœa, directly due to the giving of aperients on the 5th day, when he had five stools, and on the 9th day, when he had seven stools The difficulties of treating in an oxygen tent a delirious patient with diarrhœa can hardly be exaggerated

Purgation in Acute Disease

When these things occur in wards whose chiefs hold strong views about the risk of aperients in acute illness, one wonders what disasters occur elsewhere. Quite frankly, such accidents are usually due to allowing the administration of aperients to fall into the hands of the nursing staff I am well aware of the difficulties inherent in the relationship between an inexperienced house officer and an experienced ward sister But the house man should remember that experience does not always teach The nursing type of mind, being feminine, tends to be conservative , it holds fast to the orthodox and avoids experiment because of its dangers On the other hand, nurses are good observers, prepared to be persuaded by results, and with a little tact difficulties of this kind can usually be surmounted. An aperient is a drug A nurse may not administer a drug unless it has been ordered in writing The doctor who permits errors by ordering aperients *p r n* is himself directly responsible It must be admitted that text-books of medicine rarely emphasise these dangers and in some ways have hardly advanced from the old purgation calendars

In acute tonsillitis "an initial dose of calomel, 2 to 4 grains, should be administered and followed by a saline aperient " (Barwell 1933)

In cerebro spinal fever "it is frequently necessary to use purgatives If the patient is comatose early in the disease, when treatment is beginning, it may be *advisable to give 2 minims of croton oil* " (Horder 1933)

In pneumonia "it is important to get good action of the bowels in the early stage of the disease The large bowel should be completely emptied Later on, the less the patient is disturbed in any way the better" (Chandler 1936)

I am glad to be numbered amongst those who have never administered croton oil. The sense of these statements appears to be that one should only purge at the onset of a febrile illness, before the patient becomes dehydrated The following method of eliminating an imaginary toxin in eclampsia needs a good deal of stomaching —

"If we knew what the toxin was we might be able to *administer an antidote, but at present the* best we can do is to hasten its elimination from the system through the ordinary channels of excretion, viz., the bowels, the kidneys, and the skin The lower bowel should be cleared out as quickly as possible by large enemata and the irritating contents of the stomach should be washed out by the stomach tube Sulphate of magnesia jalap, or calomel in large doses should be given through the stomach tube when the washing out is finished or by mouth when the patient is conscious Large doses are necessary, as absorption seems to be in abeyance, nd what would actively purge the patient under ordinary onditions would hardly move her bowels in an eclamptic eizure (Jardine 1921)

In diabetic coma clear the bowels with an enema ut do not waste time on this in collapsed cases. Constipa on is usually extreme and a potent cause of toxæmia (Lawrence 1933)

The loaded bowel of diabetic coma has impressed many observers, but surely it is putting the cart before the horse to regard the constipation as a *cause* of toxæmia. It seems much more probable that the constipation is the *result* of toxæmia and deviation of water to the kidney Acidosis and alkalosis both cause dehydration It is interesting in this regard to note that alkalosis also is accompanied by constipation and that treatment of the constipation may make the alkalosis worse —

> In all cases the onset of symptoms was preceded by several days obstinate constipation Apart from any direct relationship there may be between constipation and *the onset of alkalosis* it is possible that there may be an important indirect connexion between the two The proportion of magnesium oxide or carbonate is often increased in cases of peptic ulcer as a convenient means of correcting constipation without incurring the disadvantages of more drastic purges—a practice which owing to the high alkalinity of these magnesium salts, may well determine the onset of alkalosis ' (Oakley 1935)

In the treatment of uræmia, purgation is no longer recommended Osman (1936) writes The fluid balance in the body and particularly the volume of urine excreted, should never be upset by the giving of purges and Sir W Langdon Brown tells me that in the next edition of Price s Medicine the use of purges in uræmia will no longer be recommended.

Pre operative Purgation

Surgical operations provide one of the best examples of an acute illness or emergency for which careful plans can be laid Surgeons have such a surfeit of physiology in the primary fellowship examination that they may be forgiven a revulsion from it afterwards Nevertheless physicians have much to learn from surgeons about the practical application of physiological principles in the prevention and treatment of dehydration My researches into the customs of my surgical colleagues have revealed a curious mixture of the medieval and the modern in the attention paid to the bowels in patients undergoing operative treatment —

> It is necessary to take an ounce of castor oil the night before tonsillectomy or similar operation on the nose and throat
>
> Patients with Graves s disease are no longer purged before thyroidectomy as they sometimes died of diarrhœa when this was done
>
> In other operations outside the abdomen aperients such as castor oil or senna and salts are given on the two nights before operation, and again 48 hours after operation and on each succeeding night
>
> If the operation is inside the abdomen but the stomach or bowel is not cut the same ritual is followed with the addition of an enema 12–36 hours after operation
>
> If the operation is on the stomach or duodenum there is no pre-operative drugging but an enema of 1 quart of plain water is given at least two hours before operation A simple enema is given 24–36 hours after operation and then daily for the first five days at any rate Sometimes liquid paraffin 2 drachms b d is given by mouth from the third day

I learn that in gastric surgery "the giving of cathartics is contra indicated because the effect of them is to dehydrate the patient irritate the colon and cause post-operative gaseous distension (Eusterman and Balfour 1935) I should have thought that what was bad for a duodenal ulcer was bad for a femoral hernia, but it appears that the surgeon like the physician, still purges any unfortunate patient who is robust enough to stand the strain Only when experience has shown that purgation may be lethal is the bitter cup withheld. Can we wonder that disturbances of bowel habit so often date from a surgical operation ? I take the following purgation calendar from the current practice of rectal surgery :—

> *If for operation on Monday :—*
>
> | | |
> |---|---|
> | Haustus sennæ co 1½ oz. | Thursday 6 P M. |
> | Haustus sennæ co 1½ oz. | Friday 6 p.m |
> | Ol ric 1½ oz. | Saturday 6 P.M. |
>
> Enema saponis Sunday morning and evening
>
> Enema saponis Sunday midnight s o.s and one or two as necessary Monday morning
>
> Patient is kept on fluids, jelly and custard all Sunday Haustus catechu co., 1 oz. to be given 6 A.M and 10 A.M Monday morning
>
> *Fluid diet after operation until bowels open*
>
> Liquid paraffin b d to start on 4th day (morning)
>
> Fourth day evening at 6 P.M. olive oil enema, 10 oz. run in slowly
>
> 12 midnight ol ric 1½ oz
>
> Patient to be kept on paraffin with or without phenolphthalein afterwards

One can hardly imagine a method better calculated to secure a wet and messy large bowel than the early days of this régime Surely the obvious way to keep the large bowel clean is to give the patient a low residue diet and wash out the colon from below It reminds me of the following recipe for expelling tapeworms The expulsion of worms like the hunting of the badger, has become a rare sport in Great Britain but it might nevertheless be conducted on more humane lines

> Fluid diet for three days initial dose of castor oil and daily dose of magnesium sulphate for three mornings On the fourth morning give extract filicis liq Two hours later give magnesium sulphate ½ oz. in water (Livingstone 1935)

Hæmatemesis and Melæna

During the last two years I have been specially interested in the treatment of hæmorrhage from the stomach and duodenum. I need hardly remind you that these patients are often severely dehydrated and in bad cases the blood urea is raised. The orthodox treatment is to forbid food and drink by mouth for 48 to 72 hours and to give fluid by the rectum. On this account it is customary to wash out the large bowel early in the illness My own treatment is unorthodox, inasmuch as I feed the patient by mouth from the onset, giving approximately 2500 c.cm. of fluid diet every 24 hours I do not give fluid by rectum as I was greatly impressed by Cullinan and Price s (1932) observations on the effects of enemata in alimentary hæmorrhage :—

> The fetish of giving large numbers of enemata is dangerous and to be deprecated This applies especially to the giving of enemata in the early days of treatment when recurrence is most likely to occur Hæmorrhage appeared to follow closely in many of these cases the giving of the first enema. In 73 cases enemata were given before the sixth day and 7 of these were rapidly followed by further hæmorrhage. In each of these cases the hæmorrhage would appear to have ceased before the giving of the first enema and the recurrence to have been excited by it In certain of the cases where this therapy was started early hæmorrhage followed subsequent enemata Thus in another 7 cases recurrent bleeding took place at a date when the danger of recurrence

is usually past and was shortly preceded by the giving of an enema We believe that these recurrences also may well have been excited by the enemata Only 17 cases received their first enema on or after the sixth day, all without harmful consequences "

Apart from the initial melæna, which does not occur in all cases, the bowels are not opened naturally for some days after a gastroduodenal hæmorrhage The constipation is not entirely attributable to morphia, as we have observed it in patients who have not received morphia Moreover, the bowel is very refractory to aperients for one or two weeks after a hæmorrhage, and quite a strong aperient, such as ½ oz of magnesium sulphate in 1 oz of infusion of senna twice daily, may fail to act for several days I have avoided aperients, and have not begun the use of enemata until between the fifth and the tenth day Liquid paraffin has usually been started by mouth about the end of the first week, but it has been as long as the eighteenth day before the bowels have acted naturally My results, which I hope to publish soon, have been very satisfactory There has been no discomfort or pain attributable to the constipation The tongue has remained clean or white from the milky diet, there has been no fœtor oris, no fever, no distension The appetite has usually been good, and when nausea and vomiting occurred, they appeared to be the result of hæmorrhage and anæmia and improved after transfusion

Conclusions

The time has now come for me to state some of my conclusions in this matter Routine purgation in acute illnesses or before operations is unnecessary and often harmful. In most acute diseases there is a tendency to dehydration Constipation is a result of acute disease and not a cause With few exceptions toxins are neither absorbed nor excreted through the bowel wall. Intestinal toxæmia is more likely to result from diarrhœa than from constipation Purgation disturbs and exhausts the patient, provokes gastro enteritis, especially in acute infections, increases dehydration and leads to uræmia in toxic states, excites vomiting, hæmorrhage, and distension in lesions of the alimentary tract Purgatives may be given in acute bacterial infections of the alimentary tract to secure elimination, and in increased intracranial pressure and status epilepticus for deliberate dehydration With these exceptions purgatives should not be administered to patients who are acutely ill.

There is rarely any hurry to get a patient's bowels open for four or five days Lubricants such as liquid paraffin can then be given to soften the fæces and enemata every 48 hours Constipation does not cause meteorism The most common cause of meteorism is handling or infection of the bowel in surgical patients It is described, but seldom seen, as a result of severe toxæmias such as pneumonia Perhaps the most important medical cause is typhoid fever, in which there is ulceration of the bowel and diarrhœa The gas, of which part is swallowed air and part is formed by decomposition of the intestinal contents, is distributed throughout the stomach and the intestine Surgeons have learnt to avoid meteorism in predisposed cases by banning anything by mouth and giving fluid parenterally In certain cases of peritonitis these measures are combined with continuous aspiration of the stomach and duodenum and repeated injections of morphia, and the bowels are kept at rest for ten days while the peritonitis resolves

Purgatives should never be given in diseases of which diarrhœa is a symptom, such as Addison's disease and thyrotoxicosis They are also very dangerous in measles, severe burns, and œdema With these exceptions one may sometimes temper science with art, for some patients become restive when the bowels are not opened naturally, even though enemata give satisfactory results, and an aperient may then do less harm than the mental perturbation It is an ancient observation that purgatives sometimes stop vomiting, and when peristalsis is upset, as in "biliousness" and similar conditions of reversed peristalsis, calomel may restore the normal gradient I should regard such a procedure as being on a par with the use of digitalis or quinidine in heart disease, a toxic drug being used to restore a disturbed neuromuscular rhythm Even though digitalis is kept in a poison cupboard while purgatives are accessible to everyone, I hope that you will never forget that purgatives are powerful and dangerous drugs One of the most important lessons we have learnt in recent years is the ease with which sick people may be killed by household remedies such as sodium bicarbonate and Epsom salts Hurst (1936) has suggested that more people have died from alkalis than from barbiturates, and I firmly believe that more people have died from purgatives than from digitalis

Summary

The purgation of patients who are acutely ill or who are to undergo an operation is often a magic ritual rather than a rational treatment Constipation is a symptom of acute illness and not a cause Patients who are acutely ill are dehydrated and dehydration is aggravated by purgation There is rarely any urgency for the bowels to act in acute illness, and when it is necessary they should be opened by enemata and not by drugs In alimentary hæmorrhage and in peritonitis there is often great benefit from keeping the bowels inactive for 5 to 10 days

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA —At a dinner held at Grosvenor House on Feb *11th* to celebrate the 70th anniversary of this hospital, over which the Duke of Gloucester presided between £3000 and £4000 was subscribed towards the reduction of its debt of £10 000

ROYAL INFIRMARY, MANCHESTER —During the past five years a deficit of £79 817 has been accumulated by this hospital and last year s deficit was nearly double that of 1935 The number of in patients admitted in 1936 was 10 902, plus 1581 to Barnes convalescent home, new out-patients numbered 20,831, and 173,339 attendances were recorded

HÆMORRHAGIC DISEASE OF THE NEW BORN

A STUDY OF SIXTY-ONE CASES

By Norman B Capon M.D Liverp, F R C.P Lond.

LECTURER IN DISEASES OF CHILDREN IN THE UNIVERSITY OF LIVERPOOL HON CONSULTING PÆDIATRIC PHYSICIAN LIVERPOOL MATERNITY HOSPITAL HON ASSISTANT PHYSICIAN ROYAL LIVERPOOL CHILDREN'S HOSPITAL

Hæmorrhagic disease of the new born is important even though it is comparatively rare for it affects infants who are apparently healthy it endangers life with dramatic suddenness, and it often requires special treatment at the earliest possible moment When death is prevented and adequate steps are taken to cure the secondary anæmia as quickly as possible the infant shows no further tendency to bleed and enjoys normal prospects of health this fact should encourage all those concerned with new born babies to employ effective treatment immediately the disorder shows itself.

I have published two previous papers (1924, 1932) on this subject, based on 28 cases since then I have had a further 33 cases under my care and I propose to summarise the experience gained in the observation and treatment of these 61 patients 48 of whom were seen in the Liverpool Maternity Hospital 6 in the Royal Liverpool Children's Hospital and 7 in private practice In the 61 cases, there were 5 deaths and 56 recoveries.

NOMENCLATURE AND DIAGNOSIS

The name hæmorrhagic disease of the new born is not entirely satisfactory but while the cause of the condition remains unknown a better title cannot be given at least it is descriptive, but it must be used strictly and not applied to examples of neonatal hæmorrhage which are clearly secondary—e g slipping of umbilical ligature trauma sepsis syphilis or genital crisis of the new born Admittedly it may be impossible to exclude in any individual case the possibility of some of the above causes and a perusal of my case records (Table III) may invite criticism regarding the inclusion of a few of the cases but I have excluded from this study all examples of neonatal hæmorrhage which had an obvious primary cause.

The syndrome is quite clear-cut and there is seldom any difficulty in diagnosis Slight confusion is sometimes caused by (1) the infant who having swallowed maternal blood during birth or from the breast returns the blood by vomiting or passes it rectally and (2) the infant who develops an acute enterocolitis with blood in the motions. The first shows no general effects of hæmorrhage while the second suffers from diarrhœa and the motions contain fairly large amounts of mucus tinged red.

SOURCE OF BLEEDING

In most cases the chief bleeding is from the alimentary tract as will be seen from Table I:—

TABLE I—*Source of Bleeding*

Melæna alone	34
Melæna with hæmatemesis	21
Melæna with hæmatemesis and epistaxis and submucous (palate) bleeding	1
Umbilical hæmorrhage	1
Umbilical and submucous (palate) bleeding	1
Vaginal hæmorrhage	1
Bleeding from umbilicus urethra, and nose and submucous in mouth	1
Bleeding from umbilicus and vagina under mucous membrane of mouth and vulva and subcutaneous	1
	61

ÆTIOLOGY AND INCIDENCE

A typical case, with sudden and severe melæna closely resembles hæmorrhage from a peptic ulcer in adult life Many observers (e g Thelle 1910 Bayer 1929) have described ulcers found post mortem in these cases and I myself have seen several autopsies at which ulcerative erosions of gastric or duodenal vessels have been clearly demonstrated. No satisfactory explanation of these ulcers and erosions has yet been offered; it is of course possible that they are secondary to hæmorrhage in the submucous layer of the alimentary tract and in that case the ulcers must be regarded as secondary rather than primary It seems clear that there must be a general cause acting in those cases showing several sites of bleeding at the same time and even if the view is accepted that most cases of melæna are to be ascribed to hæmorrhage taking place from the base of a primary ulcer it is remarkable that, when the patient survives the ulcer always heals rapidly

Much work remains to be done upon the morphology and biochemistry of the blood in these cases the reports to date are conflicting, and further investigation will probably show that the disease may be subdivided into several types

Frequency—I can calculate the frequency only on the 48 cases seen in the Liverpool Maternity Hospital. During the period under review (January 1923 to September 1936) there were 19 421 live births in that institution hence the frequency of the condition was 1 in 405

Sex—Of the 61 infants 36 were females and 25 males.

THE MOTHER AND THE CHILD

Maternal and obstetrical influence—The parity of the mother is shown in Table II —

TABLE II—*Parity of Mother*

Primigravida	30
Second pregnancy	14
Third pregnancy	8
Fourth pregnancy	1
Later than fourth pregnancy	7
Not recorded	1
	61

It is not possible to draw any conclusions regarding the influence which place in family may have upon the occurrence of the disease. I do not think that the age of the mother or the type of labour have any bearing on the condition. In many cases the pregnancy and labour were quite normal but there were also examples of maternal toxæmia breech delivery forceps delivery induction, and Cæsarean section.

Condition of infant—The babies were usually full term and of average weight. The birth weights were as follows —

1	Under 5½ lb	5 cases	Average weight 5 lb 1½ oz Smallest weight 4 lb 7 oz
2	5½ lb to 9 lb	45	Average weight 7 lb 1½ oz.
3	Over 9 lb	4	Average weight 9 lb 4 oz. Heaviest weight 9 lb 8 oz
4	Unstated	7	

Age at onset of hæmorrhage—For 59 cases the average age of the child when bleeding began was 41½ hours. In 2 cases it had a late onset, one at 120 hours and another at 288 hours after birth.

PROGNOSIS

Prognosis is very difficult because it must depend in part upon the (unknown) cause of the condition But at present it appears that prognosis at all

TABLE III—SUMMARY OF CASES

Case No	Sex	Pregnancy	Weight	Pregnancy and labour	Age in hours when bleeding began	Type of hæmorrhage	Special treatment (Footnote (a))	Result (Footnote (b))	Additional notes
			lb oz

(*d*) (Case 45) Blood examination (Dr R Chadwick) at time when slight hæmorrhage had just started Bleeding-time, 85 sec coagulation time 2 min , red cells 5 440 000 platelets abundant; red cells apparently normal white cells 13 600 (polymorphs 51 lymphocytes 43 % large mononuclears 1 % eosinophils 1 basophils 1 % transitionals 3 %)

(*e*) (Case 4) Blood examination (Dr Chadwick) red cells 2,500,000 hæmoglobin 40 %; bleeding-time 2 min coagulation time 3½ min platelets 140 000 white cells 12 600 (polymorphs 75 % lymphocytes 17 % transitionals 8 %) normoblasts seen per 100 white cells Red cells show a little anisocytosis and polychromatophilia

(*f*) (Case 50) Paternal grandfather and great-grandfather were said to be bleeders Two transfusions were given and when the first was undertaken the patient seemed moribund—colour white like paper air hunger gasping and sighing respirations

(*g*) (Case 51) On admission he was intensely exsanguinated and semicomatose; and bright red blood was coming from anus An intramuscular injection (10 c.cm) of blood was given while arrangements were being made for transfusion but the child died before this was begun

(*h*) (Case 57) Transfusion was not given until 36 hours after the bleeding began By then the baby was extremely anæmic and dyspnœic and was thought to be moribund Hæmorrhage ceased at once and the patient's general condition improved very quickly Weight at 4 months of age—14 lb events in the moderate and severe cases, is influenced chiefly by the rapidity and thoroughness of blood treatment Consideration of my cases does not indicate that maternal influences, such as the age of the mother or the character of pregnancy and labour, affect prognosis, while it is noteworthy that infants of small weight were not specially vulnerable Of the five who died, one (a twin child) was 5 lb 2 oz in weight, but the other fatalities were all in full term babies of average weight Four children who weighed less than 5 lb 8 oz at birth recovered

TREATMENT

The mild form of the disease is undoubtedly self-limited, and the child will probably recover without any special treatment Cases of average severity seem to respond satisfactorily to the intramuscular injection of human blood, but having admitted that the disease tends to be self limited, it is obviously difficult to decide whether special treatment has played any definite part in the recovery

Severe cases are urgently in need of intravenous blood transfusion, which is undoubtedly life saving It is not yet certain that these transfusions of blood have a specific action in controlling the hæmorrhagic disease, but even if they are not specific in their effect, at least they usually preserve life until the bleeding tendency has passed. Thus any criticism of this treatment is of theoretical rather than practical interest.

It is impossible to form any definite opinion whether a case, when first seen, is likely to be of slight, moderate, or severe degree, hence very close observation is essential.

The details of treatment given to the first 28 cases are set out in my second paper (1932), added experience has suggested certain alterations and modifications, and I shall therefore deal with the treatment of the last 33 examples only Of these—

(1) *Slight or moderately severe* cases (25) were treated as follows —

Blood injected intramuscularly	23
Blood not given	2

The average dose of blood given to each child was 36 6 c cm There were two deaths one of these children received 100 c cm of blood and the other 66 c cm In both cases I criticise my treatment, for these babies should have been given intravenous transfusions of blood

(2) *Very severe* cases (8) received intramuscular injections of blood (average dose 47 c cm), and when it was obvious that the hæmorrhage was not controlled, intravenous injections of blood were given The average dose was 78 c cm and all these children recovered, though two were thought to be moribund when the transfusion was given, and in one case the operation was suspended for a few moments because the baby appeared to have died

We have not met with even the slightest ill effects from blood transfusion in these cases, but it is admitted that the number of cases so treated is comparatively small.

The general plan of treatment now adopted is as follows —

1 Umbilical or superficial hæmorrhage receives *local treatment*—e g, retying of cord, application of adrenaline or tannic acid. Viper venom would be worth a trial, but I have not had an occasion for using it in this type of case

2 *General treatment* includes observation of rectal temperature and heart rate at half hourly intervals, application of warmth by hot bottles or electric blanket complete rest in the cot, and 5 per cent glucose in drachm doses, given orally by spoon, to allay thirst

3 An *intramuscular injection* of human blood (20 c cm) is given The blood need not be typed but it should be citrated (sodium citrate two third grain to 10 c cm blood) The injection may be made into the outer aspect of the thigh and it is wise to introduce the needle below the midpoint of the thigh, in a cephalic direction in order that the puncture may be outside the napkin area and so out of danger of infection When it is necessary to repeat injections different masses of muscle should be used, for instance the deltoid region If bleeding is not severe, as judged by the colour and general condition of the patient as well as by the total volume of blood lost, further special treatment may not be required If the child becomes restless again, or if more hæmorrhage occurs within two hours after the injection, a further dose (20 c cm) of blood is given intramuscularly, and provisional arrangements are made for a transfusion These include (*a*) notification of an operator skilled in this type of treatment, (*b*) blood grouping of infant and donor, and cross matching of their bloods, (*c*) examination of the patient to find the most suitable vein, preferably on the scalp or foot

4 If intramuscular injections have not been successful, a *transfusion* of 60–100 c cm of compatible blood is given It is seldom that transfusion has to be repeated In future blood transfusions will probably be used more frequently as treatment for the anæmia secondary to hæmorrhage

5 In regard to the *feeding* of the child, there seems to be no danger in allowing the baby to return to breast milk as soon as the bleeding has ceased, this course is certainly less harmful than withholding fluids for fear that an ulcer may bleed again if alimentary peristalsis is stimulated.

6 Measures directed to the *repair of anæmia* and depleted blood-volume are started two or three days after bleeding has ceased, they are important because an anæmic infant is in constant danger of infections and of parenchymatous degenerations in vital organs—e g, myocardium, liver, and kidneys In severe cases, a blood transfusion (50 to 75 c cm.) should be given, and in all cases iron (one grain of iron and ammonium citrate, in mixture form, twice daily) and a concentrated liver extract (one half drachm twice daily by mouth) are beneficial. Later, full attention should be given to the provision of vitamins, and in the winter months treatment by artificial light may be ordered

In conclusion I wish to thank the honorary surgeons and assistant surgeons of the Liverpool Maternity Hospital for allowing me to treat their cases and I am indebted to my clinical assistants (Drs Kathleen Wadsworth, W F Gaisford, and Muriel Duvall) and to the resident medical officers for their loyal coöperation Miss I Forshall, F R C S E, has performed most of the blood transfusions and it will be evident that the successful treatment of the severe cases was largely due to her conscientious assistance and technical skill

Cases other than those treated in the Liverpool Maternity Hospital were referred to me by the following, to whom I wish to express my thanks (case number shown in parentheses) Drs Dingwall Fordyce (8), William Johnson (45) G A Garrett (29), W D Peock (47), E R Evans (50), L Earlam (51), H T Nixon (11 and 26) B A Cowan (25) E L Roberts (27) J W Cowen (57), R Jones (58), and the late Dr C G Skinner (24)

EFFECTS OF PROLONGED ŒSTRIN-STIMULATION ON THE CERVIX UTERI

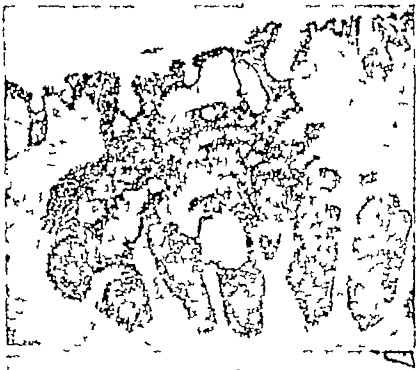
BY S ZUCKERMAN, D Sc M R C S Eng
BEIT MEMORIAL RESEARCH FELLOW
(*From the Department of Human Anatomy Oxford*)

THE reputed carcinogenic power of œstrogenic substances has lately been discussed in this journal in relation to possible dangers in the clinical use of œstrin [1] So far the histological changes induced in the reproductive organs of women and monkeys by excessive or prolonged dosage with œstrogenic substances have not been considered by those who have participated in the controversy The evidence of carcinogenesis is derived mainly from the study of cancer strains of mice and refers chiefly to the mammary glands More recently Loeb and his co workers [2] have recorded a single instance of cancer' arising during a course of œstrin injections in the uterus cervix and vagina of a mouse belonging to a strain in which spontaneous cancer of any kind is rare According to Perry [3] cancer of the uterus is a very uncommon finding in small rodents and she describes three cases in which it developed after 6–10 months of treatment in mice which she was painting with benzene solutions of œstrone and of 1 : 2 : 5 : 6 dibenzanthracene She does not state whether or not the strain she was investigating has a high incidence of spontaneous cancer There is a likelihood that it has since 43 per cent of the colony developed carcinoma of the breast Loeb and his co workers are careful to point out that the change they describe cannot be categorically defined as malignant in view of the impossibility of knowing whether or not it would have continued if the administration of œstrone had been stopped Perry on the other hand, not only declares the change in her animals to have been cancer but also states without giving the grounds for her belief that it would not have occurred if only dibenzanthracene had been given

Both women and monkeys react to prolonged and massive dosage of œstrone by the development of cystic endometrial hyperplasia [4] The condition does not extend more caudally than the isthmus uteri, and competent authorities agree that the hyperplasia is in no sense a predisposing cause to uterine cancer [5] Furthermore œstrogenic changes can be reversed by withdrawing the œstrogenic stimulus or they can be counteracted by means of some substance such as progesterone or testosterone

Certain changes that are simultaneously produced in the cervix uteri of monkeys have however been regarded with suspicion and it is necessary to consider them carefully Overholzer and Allen [6] injected a group of six ovariectomised rhesus monkeys (*Macaca mulatta*) twice daily for periods varying between 16 and 90 days with from 50–100 rat units of œstrin About once a week the cervices of these animals were traumatised by means of scissors and in addition metal clips were attached to the cervices of some of the group (the number treated in this way is not stated) Towards the close of the experimental period three of the animals were also given an extract of corpus luteum A seventh ovariectomised monkey was subjected only to œstrin and corpus luteum treatment for 51 days and was killed 33 days after the cessation of all injections An eighth castrated monkey was subjected only to cervical trauma for 86 days. All the animals showed some hyperplasia of the cervical epithelium and in most of them metaplasia had also occurred the typical cells being replaced by clumps of stratified epithelium which had invaded the myometrium Overholzer and Allen regarded these changes as precancerous and accordingly submitted their sections to Dr Ewing of Cornell University for an opinion Dr Ewing's report was that the changes should be regarded as precancerous or as early established cancer [6] It is important to note that the metaplasia occurred not only in the animals that were both traumatised and given œstrin injections, but also in the one that was given œstrin and not subjected to cervical trauma Indeed, Dr Ewing's most unfavourable report applied to the latter animal It is also of interest that the cervix of this animal showed many regions of infection, in addition to epidermization and areas of atypical epidermoid cells

The process of epithelial metaplasia that occurs in the cervix of monkeys as a result of excessive œstrin stimulation has since been studied by Engle and Smith,[7] who injected four ovariectomised rhesus monkeys daily with 200–800 rat units of œstrin for periods of 60 80 110 and 170 days respectively All four animals exhibited the same process of metaplasia observed by Overholzer and Allen The severity of the process was neither correlated with the total amount of œstrin administered nor with the length of the periods of injections Engle and Smith point out that the squamous cells in the cervix are not connected with the vaginal epithelium They



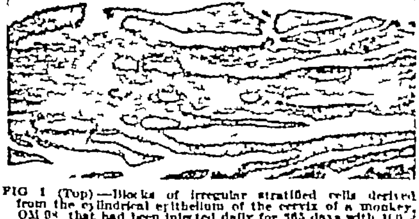


FIG 1 (Top)—Blocks of irregular stratified cells derived from the cylindrical epithelium of the cervix of a monkey, OM 94 that had been injected daily for 365 days with 100 γ of œstrone (× 45)

FIG 2 (Bottom)—Corresponding part of cervix of another monkey OM 95 that had been injected for a similar period with œstrone but with interruptions between courses of injections, showing normal epithelium (× 45) also believe that the replacement of the normal cylindrical epithelium is effected from proliferating groups of cells along the basement membrane The metaplasia is an orderly process, and it is the opinion of Engle and Smith, and of a number of pathologists and gynæcologists who examined their sections, that the change presents "few of the characters of malignancy," no single instance being seen "where the direction of growth penetrated the supporting tissue" This opinion is thus contrary to that submitted by Overholzer, Allen, and Ewing

AUTHOR'S OBSERVATIONS

A rhesus monkey (OM 98) in my own colony was injected daily with 100 γ of œstrone for 365 days—a period which so far as monkeys are concerned is twice as long as any thus far reported The animal's cervix shows the same condition of metaplasia that is described above (Fig 1)

As a rule the change in the epithelium begins in the deepest parts of the glands, which become filled with a plug of altered epithelial cells (Fig 3) In some regions the normal cylindrical epithelium is heaped, and sometimes the plates of invading cells appear to be more columnar than squamous in character especially in the peripheral parts of the metaplastic patches No epithelial pearls occur in these patches which do, however, occasionally show degenerative changes Mitoses are uncommon There are no areas of infection, but leucocytes are occasionally seen both in the blocks of squamous cells, in the myometrium, and between the cells of the surface and glandular epithelium

The process of epithelial growth appears altogether orderly, and the metaplastic patches are everywhere insulated from the myometrium by a definite basement-membrane (Fig 3) In places the insulating substance is a thick homogeneous layer, which is presumably derived from the collagenous connective tissue, and which contains no nuclei (Fig 5)

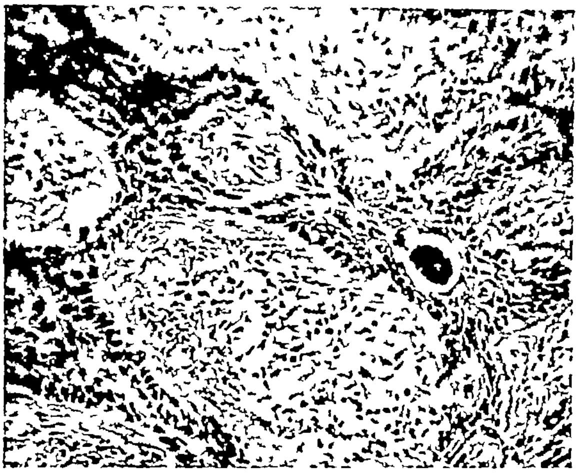

FIG 5 (OM 98)—A thick homogeneous layer of 'ground substance free of nuclei insulates the blocks of metaplastic cells from the myometrium (× 250)

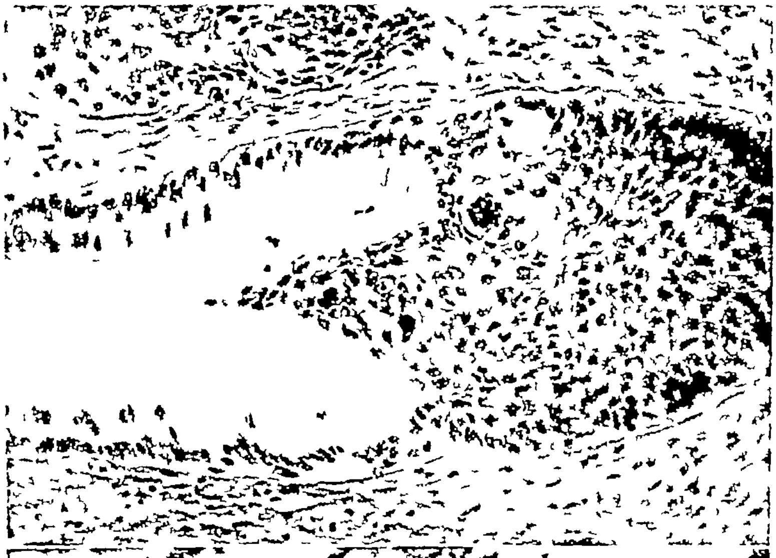
Neither Prof G W Nicholson of Guy's Hospital, nor Dr H M Carleton of Oxford, who very kindly examined the sections, regard the epithelial changes as either malignant or precancerous Prof Nicholson commented on the resemblance of the specimen to the condition of erosion of the cervix in women

The fundus uteri is in a condition of cystic endometrial hyperplasia and has been discussed elsewhere [8] The vaginal epithelium presents the usual characters that are associated with œstrogenic stimulation, being deep, extensively cornified and in process of rapid desquamation The mammary glands, as well as several other regions of the body, were also examined microscopically, but no pathological changes were observed. It may also be noted that the animal showed no adverse reactions to the treatment during the year she was under injections and that in this respect she was no different from some 30 other monkeys in my colony that have been injected daily with œstrone, with almost no remissions, for periods of between one and two years

It would be expected, a priori that the changes in the cervix, like those induced by œstrin in the uterus or prostate are reversible It may however be noted that one of Overholzer and Allen's animals exhibited a metaplastic cervical epithelium 33 days after it was last injected with œstrone The total amount of hormone given was 2802 5 rat units My own experience differs in this respect from theirs A rhesus monkey (OM 95) received ten courses of œstrone injections over a period of 399 days the total amount of hormone administered being 230,100



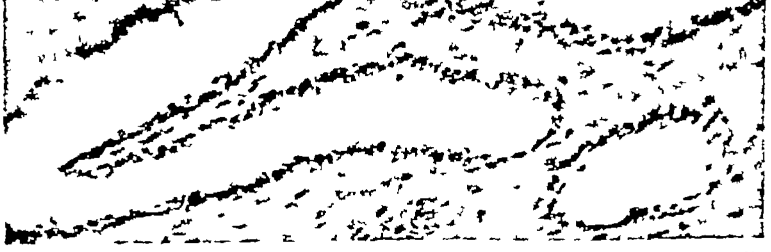


FIG 3 (Top)—(OM 98) A plug of cells derived from the cylindrical epithelium fills the base of a cervical gland The basement membrane is well shown (× 250)

FIG 4 (Bottom)—(OM 95) Normal cervical epithelium (× 250) international units (at least ten times the amount given by Overholzer and Allen). The first seven courses lasted 40 days each and the last three 14 the intervals between the courses being the latent periods that precede the uterine bleeding which follows the administration of œstrone The animal was given 322 daily injections during the entire experimental period of 309 days The uterus was removed on the fourteenth day following the last injection.

The cervix of this animal is much smaller than that of the one which received 365 successive daily injections (cf Figs 6 and 7) Moreover its epithelium is very little if at all different from the normal (Figs 2 and 4) There are no plates of squamous cells of the kind seen in OM 98 and no signs of metaplasia except in the region where the squamous vaginal meets the cylindrical cervical epithelium and where an intermixture of squamous and columnar elements cannot be regarded as an entirely unexpected finding

The line of transition of cylindrical and squamous vaginal epithelium is normally very variable and on the basis of a study of 11 specimens recovered from rhesus monkeys Clark and Corner [9] have suggested that the zone of transition rises with increasing age According to Koff,[10] on the other hand it descends towards the vaginal fornices in human fœtuses during organogenesis Koff quotes Robert Meyer's observation that the junction of vaginal squamous and cervical cylindrical epithelium always occurs at first in the cervical canal, and that the cervical epithelium then destroys the stratified cells as far as the external os. It was Meyer's belief that in about one third of cases the process of replacement is so pronounced as to produce a condition of congenital erosion of the cervix. Whichever way the evidence is regarded it thus indicates that there is a conflict between the two types of epithelium in the cervical canal I have suggested elsewhere [11] that squamous hyperplasia can in general be regarded as a primary response of tissues in whose development the epithelium of the urogenital sinus has played a part If the view that the primate vaginal epithelium is derived from the sinus is accepted (for discussion see [12]) the occurrence of metaplasia in the cervix following œstrogenic stimulation becomes understandable

Even if such metaplasia be regarded askance from the clinical point of view it is plain that the possibility of provoking such a change should not be considered a reason for advising against œstrin therapy in general For in the first place it has to be remembered that the effects of œstrin are reversible so that the normal condition of the tissues can be restored by withdrawing the hormone ; and in the second there can be little need in clinical practice for prescribing the hormone continuously over prolonged periods The healthy condition of the uterus of OM 95 and the absence of any adverse effects in other monkeys that have received œstrin in successive courses of injections for periods of from one to two years suggest that the best way of administering the hormone clinically would be in similar courses of injections lasting 2–4 weeks, intervals being left between the separate courses to allow of œstrin withdrawal uterine bleeding

SUMMARY

Metaplastic changes occur in the cylindrical epithelium of the cervix uteri of rhesus monkeys receiving œstrone injections for long periods (about three months), the columnar epithelium being replaced in places by squamous cells which invade the myometrium The metaplastic process is an orderly one and the patches of squamous cells are insulated by a remarkably thick basement membrane The process does not possess the general characters of malignancy and it is reversible Thus it was not displayed by a monkey that was given œstrin daily in successive courses of treatment (totalling 322 daily injections) over a period of 300 days It is suggested that in clinical practice the hormone should be given in courses of 2–4 weeks with intervals between courses to allow of œstrin withdrawal uterine bleeding

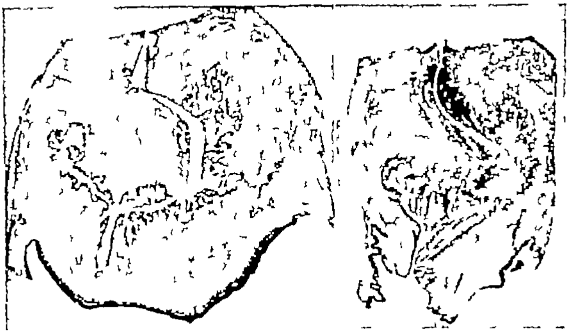

FIG 6 (Left) —Cervix of monkey (OM 98) that received œstrone daily for a year (× 3)

FIG 7 (Right) —Cervix of monkey (OM 95) that received œstrone for a similar period but in successive courses of injections (× 3)

The expenses of this study were defrayed from a grant kindly given by the Medical Research Council The œstrone was generously provided by the Organon Company

A COMPARISON BETWEEN THE ADSORPTIVE ACTION OF KAOLIN AND KAOLIN-ALUMINA MIXTURE ON FÆCAL BACTERIA

By William Smith, M.D Camb
PATHOLOGIST TO THE MILLER GENERAL HOSPITAL, GREENWICH

Kaolin (aluminium silicate) has been used for centuries in the East for the treatment of epidemic cholera Walker (1921) showed that its curative action, in addition to being of a mechanical nature, was due to its power of adsorbing bacteria He also suggested that this inert substance acted as a filter in the intestine, and thus prevented absorption of toxic substances into the blood stream Braafledt (1923) determined that kaolin will adsorb large numbers of bacteria in fluid media, and also that it neutralises and thus prevents the toxic effects of such organisms as *Bacillus typhosus*, *Bacillus para typhosus*, *Bacillus enteritidis* Gaertner, *Bacillus dysenteriæ* Shiga, and the vibrio of cholera, he also demonstrated its successful therapeutic use in such infections as cholera, dysentery, ulcerative colitis, and acute enteritis

Kaolin, a chemically inert finely divided powder, has a very large surface combined with a high adsorptive power An apparent disadvantage of its use in treatment, however, lies in the fact that kaolin alone in a liquid suspension settles down fairly rapidly, and forms a mass which cannot readily be completely broken up If this " clumping " could be prevented by the addition of a substance which would hold the kaolin in suspension, and thus allow it to act as completely as possible, much improvement in its adsorptive powers might be anticipated

It has been shown by Crohn (1929) that powdered aluminium hydroxide can be used as a substitute for other alkaline substances in the treatment of peptic ulcer Aluminium hydroxide, however, possesses its greatest adsorptive power when in the colloidal state (gel), its action in the alimentary canal being due to this property of adsorption, and not to chemical neutralisation A preparation containing a suspension of kaolin in aluminium hydroxide gel (kaolin alumina mixture) therefore suggested itself Such a preparation is found to be neutral, has great adsorptive properties, is tasteless, and odourless Swalm (1934) showed that such a mixture, when added to a fluid medium, produces a much more voluminous and flocculent sediment than is the case when kaolin alone is used. The supernatant liquid of a suspension of fæces, in vitro, can be completely decolorised by a kaolin alumina mixture, but only incompletely by an equal weight of kaolin alone.

EXPERIMENTS

In view of the finding that a kaolin alumina mixture apparently is more efficient, as regards its adsorptive power, when compared with kaolin, it became of interest to determine whether such a mixture did, in fact, adsorb a greater number of bacteria than kaolin alone The kaolin alumina mixture used in the following experiments contained 20 per cent aluminium silicate (kaolin) and 2 5 per cent aluminium hydroxide gel. This was a similar strength to that used by Swalm

In the preliminary experiments directed to this end, suspensions of fæces in water were prepared, and strained through butter muslin in order to remove any extraneous matter To these suspensions equal weights of kaolin and kaolin alumina mixture were added, the resulting mixtures were well stirred and then allowed to stand for 24 hours at room temperature At the end of this period bacterial cultures were put up from which bacterial counts were made These experiments did not indicate any very definite finding as to whether kaolin or the mixture had adsorbed the greater number of bacteria

Some modification appeared to be necessary in the technique, in order definitely to determine if any difference could be detected in the power of adsorbing bacteria That kaolin adsorbs bacteria is well known, and this property is made use of extensively in medicine It seemed therefore desirable that further tests should be carried out at the temperature at which the substances are normally used—viz, body temperature—and further it seemed possible that the time factor might enter into the matter During the preliminary experiments it had also been determined that, in order to make accurate bacterial counts possible, the fæcal suspensions would have to be comparatively weak. The technique finally adopted for these experiments was the following —

A weak suspension of fæces was prepared and strained through butter muslin Three measuring cylinders of 250 c cm capacity were taken, and each was filled with the fæcal suspension (Fig 1) One of these (A) contained fæcal suspension alone, whilst to the second (B) 3 grammes of kaolin was added, and to the third (C) an equal weight of kaolin alumina mixture (Fig 1) The kaolin and kaolin alumina mixture were well stirred into the suspension The three cylinders were then placed in the incubator at 37° C, and at various intervals samples from each were taken from which bacterial counts were

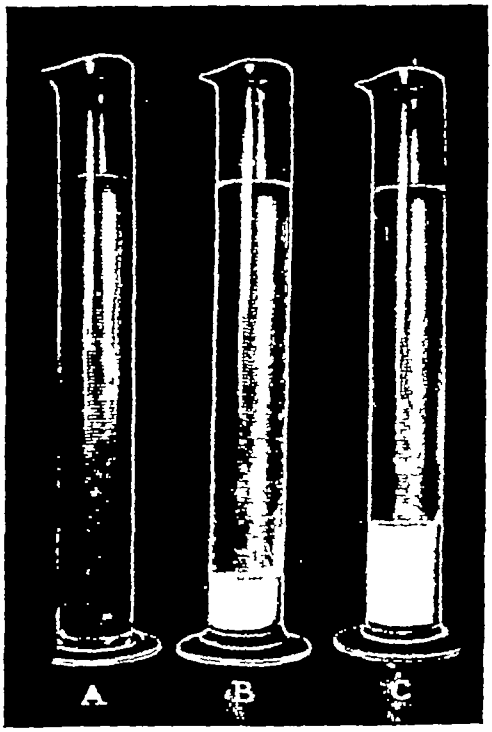

FIG 1 —Cylinders filled with (A) fæcal suspension alone, (B) 3 g kaolin (C) 3 g kaolin alumina mixture note greater bulk of sediment

made After each sample had been removed the mixtures were again well stirred and the cylinders then replaced in the incubator

METHOD OF MAKING THE BACTERIAL COUNTS

The principle was similar to that in use for making bacterial counts from samples of milk. The medium employed was peptone agar

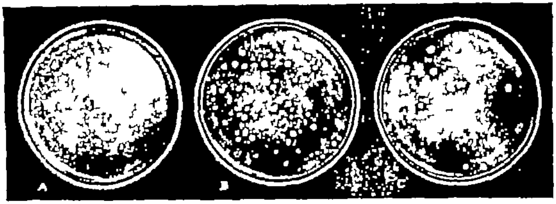

FIG 2.—Cultures prepared from different dilutions of fluid in the cylinders shown in Fig 1 (see also Table) (A) Fæcal suspension alone 1/100 dil. (128 000 bacteria per c.cm). (B) with kaolin 1/10 dil. (10 400 per c cm.) (C) with kaolin-alumina 1/10 dil (2280 per c.cm)

This was melted and then cooled to approximately 45° C Accurate quantities of the sample to be tested were now added the tubes containing the medium and the sample well shaken and the resultant mixtures poured into a Petri dish The medium was allowed to set and then incubation proceeded for twenty four hours before the counts were made

For each experiment varying dilutions of each sample were employed These were prepared similarly to the method used for the plate count of milk. The usual strengths used were undiluted 1/10 1/100 1/1000 of which 1 c cm of each was added to a tube of peptone agar

The actual bacterial counts were ascertained from the dilution which gave the most suitable growth for the purpose and the figures quoted in the Table were obtained as a result of multiplying the actual dilutions employed by the number of colonies definitely present in the medium.

Table showing Growth of Bacteria in Fæcal Suspensions

Cylinder	Time of incubation	Test 1		Test 2	
		Dilution of suspension	Bacteria (per c cm)	Dilution of suspension	Bacteria (per c cm).
(A)	30 min.	1/100	67 000	1/100 (Fig 2A)	1 8 000
	1 hr	1/100	102 000	1/100	170,000
	24 hrs	1/1000	3 200 000	1/1000	3,600 000
(B) Kaolin		3 grammes		6 grammes	
	30 min	1/100	19,200	1/10 (Fig 2B)	10 400
	1 hr	1/100	•1,200	1/10	7 760
	24 hrs	1/100	00,000	1/100	24 400
(C) Kaolin alumina		grammes		6 grammes	
	30 min	1/10	4 080	1/10 (Fig 2C)	2 280
	1 hr	1/10	4 040	1/10	1 880
	24 hrs	1/10	6 050	1/1	414

It was notable that when 6 g of the kaolin alumina mixture were used, not a single colony of *Bacillus coli* was obtained in the twenty four hour culture The *B coli* however were still numerous in the similar culture using kaolin alone

Using stronger fæcal emulsions having a definite coloration Swalm's findings of the greater efficacy of the kaolin-alumina mixture in decolorizing and removing the odour from the suspension as compared with kaolin alone were confirmed.

Hydrogen ion concentration—The possible explanation suggested itself that the more efficient adsorptive power for intestinal bacteria of the kaolin alumina mixture might be due to an alteration in reaction. Control experiments however showed that there was no appreciable difference between the hydrogen ion concentration of kaolin or kaolin-alumina mixture emulsions in water alone or when these two substances were added to the type of fæcal suspensions used in the above experiments.

Effect of supernatant fluids—A further possibility was that the supernatant fluids obtained after shaking kaolin or kaolin-alumina mixture may have some bactericidal value Tests made in a similar manner to those employed to ascertain the Rideal Walker coefficient were put through The same amount of a culture of *B coli* was added to varying volumes of the supernatant fluids Glucose peptone broth was used as a culture medium. In no instance even when only a small number of bacilli were introduced was any evidence obtained that the growth of the bacilli introduced had been inhibited in any degree Control experiments were made in each case in which there was no addition to the supernatant fluid.

CONCLUSIONS

Under the above conditions a kaolin alumina mixture is more efficient than an equal weight of kaolin as an adsorbent for fæcal bacteria

When an adequate amount of the kaolin alumina mixture is present an almost complete adsorption of the bacteria occurs with entire removal of the *B coli*.

The explanation of these findings appears to lie in the adsorption quality and not to be due in any way to a change in the hydrogen ion concentration or to a bactericidal effect of the supernatant fluid

I am much indebted to my senior technician Mr J W Roberts for taking the photographs from which the illustrations have been made

Clinical and Laboratory Notes

SERUM CALCIUM IN THE PSYCHOSES

By I Atkin M D D P M Lond

ASSISTANT MEDICAL OFFICER AND PATHOLOGIST PARK PREWETT MENTAL HOSPITAL

When assessing the chemistry of the blood in the psychoses care must be taken to exclude other possible causes of variation apart from that which may be due to the psychosis itself Higher calcium values have been reported in diabetes arthritis deformans and syphilis lower calcium values in nephritis bronchial asthma and uncomplicated heart failure In the present investigation therefore patients suffering from any of these illnesses are excluded In particular syphilis was excluded by a routine micro Meinicke test and kidney disease by a blood urea estimation and a microscopic examination of the urine deposit Other conditions which are well known to influence the blood calcium, such as rickets, tetany, and sprue, are not likely to be overlooked.

In order to obtain some idea of the accuracy of the technique utilised in this investigation (by the method of Kramer and Tisdall), eight solutions of known strengths varying from 7 15 to 13 32 mg per 100 c cm of calcium chloride were made and estimations carried out The error varied from + 0 55 per cent to − 3 4 per cent, the average being − 1 28 per cent

In the classification of the psychoses as they appear with the figures tabulated below, only pure clinical pictures were included, manic depressive cases with schizoid features, for example, are omitted, as well as any case where the diagnosis for some reason or other appeared to be still in doubt

Psychosis	No of cases	Range	Average
Schizophrenic	70	9·0– 9 9 10 10·0–10 9 39 11·0–11 9 20 12 1 1	10 48
Melancholic	47	8 2– 8 9 2 9 0– 9 9 15 10·0–10 9 27 11·0–11 4 3	10·07
Manic	13	9 6–11·8	10 55
Epileptic	15	9 0–11 0	10 98
Dementia paralytic	15	8 2–11·0	9 67

DISCUSSION

(1) If we take the normal range of variation as 9 to 11, it appears that there is a tendency for higher values in the schizophrenic states This confirms a recent report by Minker-Bogdanova and others (1934), who also note progressively lower values with the advance of the disease It should be noted that the great majority of the 70 cases here investigated were recent admissions

(2) Of greater interest are the findings in the manic-depressive group, which exhibit lower figures for the depressed phase and higher for the manic phase On several occasions this was confirmed by a serial investigation in a particular case, of which the following are three examples —

	Depressed phase		Lucid phase	
A	Feb 6th	10 8	March 20th	11·0
B	Feb 12th	9 1	20th	10·2
C	May 1st	9 75	August 27th	10 4

That there is a parallel relation between the blood-calcium level and the emotional tone has been frequently suggested—e g, by Laird and Stephen (1933)—high calcium values being associated with cheerful states and low with depressions Among previous reports of such a correlation in the manic depressive psychoses is that of Henry and Ebeling (1926)

(3) In the epileptic psychoses the blood calcium tends to higher values How far the epilepsy itself and/or the type of accompanying psychosis contributes to this is very difficulty to say

(4) Average values are found in dementia paralytica

I wish to thank Dr V L Connolly, medical superintendent of Park Prewett Mental Hospital for permission to carry out this investigation, and Mr S Davenport, the laboratory assistant, for help in the technical work

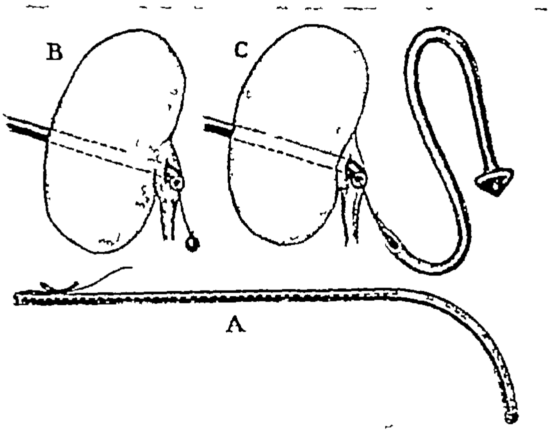
NEPHROSTOMY

BY SIR WILLIAM DE C WHEELER, F R C S I
SURGEON ALL SAINTS HOSPITAL, LONDON

TEMPORARY drainage of one or both kidneys has become an operation of comparative frequency in recent years Many cases are on record in which nephrectomy appeared to be indicated but was avoided of necessity owing to the condition of the other kidney Simple drainage often resulted in a surprising recovery Again nephrostomy is indicated when a severe operation on the lower urinary tract is contemplated, just as colostomy is employed before extensive operations upon the rectum Plastic operations upon the renal pelvis are also rendered more safe and secure if temporary drainage is employed

The following technique for drainage of the kidney has been found convenient and satisfactory in a number of cases operated upon during the past few years It is a modification of the Cabot method (Cabot and Holland 1931) The special instrument employed is a metal catheter with the top removed so as to provide a terminal eye (see Figure) A steel ball is held firmly in this eye by a thread pulled through the lumen of the catheter with a long stylet The instrument was originally designed to aid in the repair of ruptured urethra (Wheeler 1929)



A.—A modified metal catheter with a steel ball fixed in the terminal eye by means of a thread passed through the lumen

B —The renal pelvis has been incised, the ball after acting as a guide is released

C —The ball has been cut off and the thread attached to a winged catheter

The kidney is exposed, but free mobilisation is seldom necessary A scratch is made through the capsule near the middle of the convex border The instrument is passed through this minute incision via the renal cortex into the pelvis The steel ball pushes forward the wall of the latter and acts as a guide for an opening When this is made the thread is unhitched from the proximal end of the instrument The ball is now released and removed The thread is attached to a No 22 or 24 French winged catheter and pulled upon until the end of the catheter enters into the terminal eye of the metal instrument The latter is withdrawn carrying with it the rubber catheter The winged portion slips into the pelvis and should lie in a position to drain the lower calyx and to pass straight outwards through the lumbar wound without angulation No sutures are introduced to aid fixation or to close the pelvis

In about a fortnight the tube may be removed with the aid of a stylet, which with traction on the tube narrows the expanded extremity If further drainage is required a straight rectal tube is introduced immediately It must be the same length as the original catheter measured from the point where it emerges from the wound to the expanded end The winged catheter should be a shade larger than the metal instrument to ensure a tight fit in the renal substance and so avoid bleeding

By the method recommended there is no difficulty in finding the pelvis and manipulation of the kidney is reduced to a minimum

SPONTANEOUS (PATHOLOGICAL) DISLOCATION OF THE ATLAS

BY G H STEELE, M.S Lond. F R C.S Eng

SURGEON TO THE ROYAL SURREY COUNTY HOSPITAL, GUILDFORD

CASES of spontaneous dislocation of the atlas are being recognised and reported with increasing frequency and the following case appears to throw light on the ætiology of this uncommon condition about which there has been some discussion.

A boy of 7 was admitted to hospital exceedingly ill with the history that 11 days before adenoid curettage had been performed; the tonsils had not been removed on account of the presence of boils elsewhere A week later he began to complain of severe pain in the neck

On examination he was lying in bed with a slight degree of torticollis and forward displacement of the chin and screamed at any attempts at examination. He was obviously most sensitive in the region of the upper part of the cervical spine and when he altered his position, which happened infrequently on account of his pain, he held his head steady with both hands The temperature was 102 F the pulse-rate 120 and the respirations 36 A diagnosis of inflammatory atlanto-axial dislocation was made and confirmed by radiography (Fig 1)

Treatment —Under general anæsthesia the head neck, and chest were enclosed in plaster without any attempt at reduction of the dislocation. Under the anæsthetic the adenoid region was found to be still in a sloughing condition but the anterior arch of the atlas was not felt to be unduly prominent

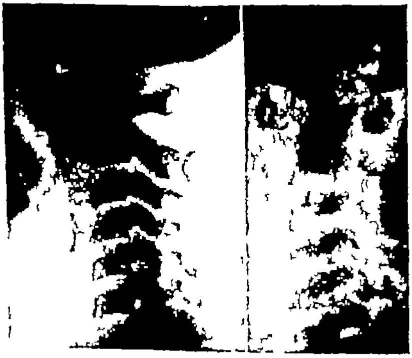

FIG 1.—Radiograms showing pathological dislocation of the atlas Left: before treatment Right: on discharge four months later: displacement unchanged but joint functionally normal.

Progress —The temperature continued to swing between 101° and 104 F and at the end of a fortnight a pyæmic arthritis of the left ankle developed as a painless swelling Arthrotomy and lavage were performed with subsidence of the ankle infection which however, flared up again a month later and was then treated by open drainage After the first operation the temperature fell to an irregular 99 F and the condition of the neck was obviously greatly improved but at the end of another month the child developed a painless pathological dislocation of the left hip (Fig 2) This was treated by means of a strapping extension of 10 lb, decreased to 5 lb after a few days when the dislocation was found to be reduced The neck plaster and the extension were removed three months after admission. The plaster could probably have been removed a month earlier as it had become loose and the head movements within a small range were free and painless but it was felt to be a useful safeguard The boy was discharged with full use of all the affected joints a month later four months after admission An X ray examination at this date showed that the amount of displacement of the atlas remained unaltered.

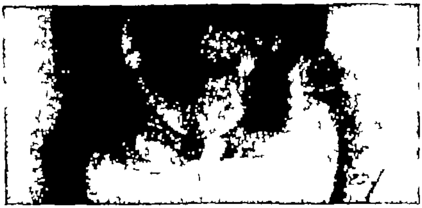

FIG 2.—Pathological dislocation of left hip in same case as Fig 1

A useful survey of reported and personal cases has been made by Watson Jones (1932) The patients are most commonly in the first decade of life and a traumatic factor is absent or was very mild. The first reported case is that of a nurse who killed a patient with such a dislocation by turning the head a little to one side while doing a dressing Another story has been told of a surgeon demonstrating a case to a class of students as a rheumatic torticollis he mentioned inflammatory dislocation as a differential diagnosis, and said it was a very rare condition which could be diagnosed by the fact that if the chin was chucked the patient died a remark which he proceeded to illustrate with fatal results. The next case was also one of torticollis Saying that in view of the rarity of the condition this could not possibly be another of the same he killed the second patient likewise

In all the cases there is an inflammatory lesion in the upper part of the neck—tonsillitis nasopharyngitis suppurating glands mastoiditis and so forth. In the case reported here there was probably a septicæmia due to the boils and this was responsible for the infection of the adenoid site The infection had probably spread backwards by direct continuity but according to Watson Jones the inflammatory focus causes a hyperæmia in the region of the base of the skull softening the attachments of the transverse ligament of the atlas which may be avulsed the hyperæmia also accounting for the decalcification of the anterior arch of the atlas that may be present Wittek (1908) calls the condition distension luxation stating that it is a distension of the bursæ between the odontoid process, the anterior arch of the atlas, and the transverse ligament, which leads to a stretching and weakening of the ligaments The inference to be drawn from *this case appears to be that the condition is similar to that of the inflammatory pathological dislocation which occurred in the hip, and in the words of* Choyce (1932)

> "*Among the chief factors making for articular strength* are the integrity of the joint surfaces and the tone of ligaments and muscles If disease has weakened any of these dislocation will readily occur As a rule in pathological dislocations several agents are at work, though usually one predominates"

The typical clinical picture is similar to that in this case A child complains of a stiff neck some days after, for instance, a throat infection, and is found to have a painful torticollis which he endeavours to protect by his own efforts The anterior arch of the atlas may or may not be felt as a prominence in the nasopharynx, and radiography is the key to the diagnosis For *treatment*, Watson Jones recommends reduction of the dislocation by extension and fixation in plaster The dislocation, however, can of necessity be only moderate in degree if the patient survives, and since the patients are usually young children—and it is astonishing how children will compensate for slight or even severe bone and joint mal alignment in the process of growth—it seems unnecessary to do more than to put the inflamed area *at rest by means of a restrictive plaster*, thus avoiding the risk of reduction Blunck (1935) and Stammers and Frazer (1933) mention cases which have been treated in this manner with good functional results

The moral of this story is that one should be on the look out for the condition among the ordinary cases of acute torticollis, if there is any doubt, a lateral radiogram of the neck will remove it

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF PSYCHIATRY AND MEDICINE

AT a joint meeting of these sections the chair was taken by Dr T A ROSS, president of the section of psychiatry A discussion on the relation between

Mental Disorder and the Activities of the Endocrine Glands

was opened by Prof F L GOLLA He supposed, he said, that no member would defend a pathogenesis of mental disorders based upon diseases of the ductless glands There was very little evidence even that the symptomatology of mental disease was influenced by endocrine disorder Recent work suggested that there were nerve cells in the diencephalon which had a secretory function, and it might be inferred that their secretion was that which had been attributed to the posterior and possibly to the anterior lobe of the pituitary body This research in itself opened a new vista of possible hormonic influences on the central nervous system A number of "nervous systems" influencing one another by internal secretions would make the work of the psychiatric pathologist easier by releasing him from the task of explaining the influence of one system on another in terms of the old biophysics—excitation and conduction There was not the faintest physiological evidence *that any particular* secretory disturbance accompanied any particular form of psychosis For once however the histologist had the satisfaction of finding that the microscope gave him information which physiological methods would not The gonadal system and particularly the testicles, would sometimes show disturbances of structure which the pathologist had a right to assume were accompanied by corresponding disturbances of function Sir Frederick Mott had shown the connexion of testicular pathology with schizophrenia Failure of testicular function was not however responsible for mental disorder Anyone who kept animals knew *that a male animal suffered loss of* function if deprived of the female for long enough Studies of eunuchs throughout history showed that their deprivation delivered them from the stress which might lead to mental disorder

Dr Golla then showed a series of slides prepared by Sir Frederick Mott, illustrating the testicular disorders associated with dementia præcox The testicle showed, progressively, reduced spermatogenesis, shrinkage of tubules, crinkling due to fibrosis interstitial proliferation, thickening of basement membrane and lipoid in the interstitial tissue For some curious reason nobody seemed to have given these observations the importance they deserved In mental disorder one was dealing with a general profound bodily disturbance of which one feature was a disorder of conduct, and another was a disturbance of the endocrine system The testicular changes, however were very striking and were never found in other conditions

If the male sex organs of an animal were wholly ablated and the animal were then given testicular extract or graft, the animal would sometimes show normal sexual behaviour It must be concluded that the testicular hormone had a particular affinity for the nervous mechanism concerned in sexual acts This was the only physiological support for a suggestion that a hormone might act directly on the nervous system The pituitary syndrome, being under the governance of the diencephalon did not offer direct proof of such hormonic influence Endocrinologists seemed sometimes to forget that every organ received a nerve fibre The central nervous system was a most labile mechanism, and, if an effect could not be produced in one way, it would invoke another An endocrine disorder might be imagined to produce a general hyper or hypo excitability but it was difficult to imagine it affecting one particular function

A paper written by Sir WALTER LANGDON-BROWN was read by Dr S LEVY SIMPSON Endocrinologists he said, since recognising the relationships of the pituitary and diencephalon were less dogmatic than in the past They realised that the endocrines and emotions influenced each other Endocrines were not a common cause of psychoses, the relationship between them had been overrated Indirectly endocrinopathy might contribute by causing disfigurements and other bodily abnormalities Endocrine stigmata were not uncommon in mental disease, but were often coincidental Psychoneurosis might often be benefited by correcting glandular disorders—

notably those of the thyroid. Thyroid medication had turned many patients from mental hebetude to normal functioning The myxœdematous patient was apt to become morose and suspicious projecting his own failures to function on to his environment Occasionally he became maniacal; thyroid in such cases was curative Hyperthyroidic patients showed irritability and a tendency to cry O cursed spite that ever I was born to set it right regarding themselves as the only righteous persons in an ill world They indulged in nerve storms. Graves's disease had been well described as a state of continuous fear Its causes were sex sepsis and emotional stress the third of these factors might act through the hypothalamus and thyrotropic hormone of the anterior pituitary Many psychological accompaniments of dyspituitarism were found both in excess and deficiency Both the pituitary giant and the Fröhlich case tended to lack inhibitions They showed off stole set fire to things and otherwise tried to compensate for their feeling of inferiority They were liable to live in phantasy Alternations of confusional insanity and glycosuria had been reported and were explicable now that the diabetogenic hormone was recognised

Addison's disease might be associated with apathy inertia irritability and pessimism Virilism from cortex tumours might cause loss of modesty and maternal instinct Fear might become a dominant feature if the medulla were stimulated Insanity from diabetes had now disappeared, but hypoglycæmia might produce mental symptoms ranging from excitement to mania and homicide In hypoparathyroidism—in addition to tetany—there might be hallucinatory disturbances Pineal tumour caused precocious mental and physical development in some instances but more often feeble mentality later associated with epileptiform manifestations Gonadal disturbances were frequent in dementia præcox An insistently expressed egoism with resentment against the unappreciative world indicated hypogonadism Very few patients with inadequate gonads escaped inferiority which might develop into psychosis At the menopause there was temporary over production of prolan in an attempt to stimulate the failing ovary A hypertrophied prostate removed normal sexual inhibitions but there was no adequate evidence for a male climacteric.

DISCUSSION

Dr A P CAWADIAS thought that Kretschmer had unwittingly confirmed Mott's work his asthenic type was the hypogonadal The male hormone and the anterior pituitary had a particular action in schizophrenia but they were not causal Every patient must be considered as an individual Many mental disorders had been described as of endocrine origin on insufficient evidence The basis of endocrinology was metabolism and biochemistry Physicians should describe the mental phenomena of endocrine disorders and needed more precision in doing so All hormones acted on the nervous system

Dr F A. PICKWORTH said that it was misleading to speak of the hypothalamus and pituitary as an endocrine unit because many other glands were influenced by or acted through the hypothalamus The pineal adrenal hypothalamus and gonad could each and all cause pubertas præcox by an influence on the hypothalamic centre The problem there was that of the relation between the hypothalamus on the one hand and the symptoms of mental disorder and the activity of endocrine glands on the other Many cases of Simmonds's disease showed separation of the pituitary lobes by colloid or septic material Pituitary activity was undoubtedly disturbed by septic material filtering through from the nose and nasal sinuses Diplococci had been demonstrated passing up into the pituitary from the sphenoidal sinus. In 31 per cent of cases examined sphenoidal sinus sepsis had been demonstrated. There was no direct relationship between endocrine activity and mental disorder; the connecting link was capillary disturbances in certain parts of the brain

Dr A S PATERSON said that the work of Kurt Richter had a direct bearing on psychiatry It was an investigation of spontaneous activity Man's activity depended on various external factors but also on internal drive and this factor had been studied in the rat In the normal rat a definite rhythm of four days was seen in the female its activity being maximum when on rut and being halved on each succeeding day No other cycle was constant The removal of certain glands—viz the pineal thymus spleen posterior pituitary seminal vesicle uterus and cervix had no effect but if the anterior pituitary were removed the rat became totally inactive Some effect was produced by removal of the adrenal and gonad but hardly any result appeared on removal of the thyroid. Injections of suitable glands greatly increased activity It seemed that this conception of a spontaneous activity was a valuable one based on scientific data It had a bearing on manic-depressive psychosis Some patients probably suffered from genuine failure of spontaneous activity

Dr T R. C FRASER described a case in which endocrine abnormalities had been found and which had been cured by removal of the abnormalities The patient a woman of thirty suffered from neurasthenia on which were superimposed catatonic attacks associated with disturbance of consciousness She had an adenoma of the pancreas and was relieved by its removal Her symptoms were not explicable in terms of her blood-sugar level.

Dr N G HARRIS pointed out that cases of thyrotoxicosis fell into three groups those in which the thyroid was the primary factor those in which the psychological side was the important one and those in which the two went hand in hand Much could be done by correlating the effects of treatment with the type of case Women with menopausal depression might have normal menstruation, irregular menstruation or none at all The effects of endocrine treatment in the varying types should be correlated.

Dr H A. PALMER said that continuous narcosis was sometimes dramatically successful in mental cases The question was whether or not the hypothalamic centres were touched in these cases It might be possible to show that barbiturates were more successful than other sedatives and this would prove that the hypothalamus was involved There was a biphasic effect something connected with the psyche and something connected with the hypothalamus If the psyche could be given ten days respite from fear by deadening the hypothalamus it would often be able to deal with the condition

Dr DORIS ODLUM referred to the menstrual exacerbation of symptoms in women This was a strong point in favour of correlation between endocrine and psychological factors

Dr LEVY SIMPSON in reply said that prolactin seemed to influence the clucking and brooding of hens, and that the pituitary prolan seemed to have some effect on sexual libido. The reciprocity of influence between mental processes and endocrines could not be over-emphasised. Shock might cause premature menopause and fear might produce amenorrhœa. Hyperadrenalism and emotion were well known to be associated; it had been said that all the emotions of a love scene could be produced by a dose of adrenaline. Many hyperthyroid cases did well on psychotherapy alone. A vagus type of hypo-insulinism might produce disorders of conduct. Loss of weight might be extreme. Anorexia nervosa threw some light on the subject, for it might present all the symptoms found in Simmonds's cachexia. One factor in their production was nervous, but the other was a vitamin deficiency. Animals on a vitamin-deficient diet showed atrophy of pituitary and adrenal—after a phase of congestion and hypertrophy. Speaking broadly of disorders of conduct and emotion, any observer must admit their frequency in endocrine disorders. They varied according to the underlying neuropathic tendency, but were definitely associated with endocrine disorders, which were by no means rare illnesses but occurred in nearly everyone. Very few had a "normal" endocrine balance. Endocrine changes were familial, constitutional, and racial. The post-menopausal woman whose pituitary and adrenal cortex had undergone hyperplasia took an entirely different and more virile, capable, original, and fearless outlook on life. She became a successful business director, perhaps the wife of the henpecked husband or the all-powerful matriarch. Another type was the pituitary adiposity of adolescence or later life: slim arms and legs, good teeth, a fascinating smile, a beautiful face and a fat body. Such a woman was loved and loving, musical, often with a rich mezzo-contralto voice, and had great social activity. She was alternately happy and sad in a manner recalling the manic-depressive psychosis. With treatment the results were often so dramatic that it was hard to assume that anything but the endocrine factor had produced the change. In other cases some symptoms remained.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

AT a meeting of the fever group of this society held on Jan. 30th, Dr. H. S. **BANKS**, vice-president, being in the chair, a discussion on

Acute Enteritis

was opened by Dr. **ROBERT CRUICKSHANK** (North-Western Group Laboratory, L.C.C.) with a brief review of the bacteriology and ætiology of the condition. In the investigation of this problem the closest coöperation between clinician and pathologist was essential. Material for examination (fæces, vomitus) should be sent to the laboratory at the earliest possible stage in the illness since invading pathogens were rarely found after the third or fourth day, although in dysenteric infections the organism might occasionally persist for several weeks. Where there was a likelihood of delay in transmitting the specimen, use should be made of 30 per cent. glycerin in 0.6 per cent. saline as a preservative. He advocated the more frequent use of the rectal swab. The patient's blood should be examined for specific antibodies between the seventh and twenty-first day. Although sometimes negative, the presence of specific agglutinins might confirm a diagnosis of Sonne or Flexner dysentery where nothing was found in the stools; a titre of 1/10–1/20 for the former and 1/50 for the latter would be diagnostic in children.

In dealing with the ætiology he suggested a division into infectious and non-infectious enteritis, although it was sometimes difficult to separate the two groups on clinical grounds. In infectious enteritis the important organisms were (i) The dysentery bacilli, principally *B. dysenteriæ* Flexner and *B. dysent.* Sonne. While the former was usually associated with a true dysentery or ileo-colitis, the Sonne bacillus might cause gastro-enteritis or dysentery. The spread of infection—and the infectivity was often great—was by human contact or convalescent carriers. (ii) The salmonella organisms, of which the most common in this country was *B. aertrycke*. Animals were the main reservoirs of infection in this group, the mouse being a not uncommon carrier of *B. aertrycke* (or *B. typhi-murium*). *B. paratyphosus* B might be associated with a gastro-enteritis. (iii) *Staphylococcus aureus*, the importance of which as a cause of gastro-enteritis had been stressed by American workers. It was frequently a milk-borne infection and in the examination of suspected food bacteriologists should not neglect to look for it.

Non-infectious gastro-enteritis might be divided into primary and secondary types, the former being synonymous with summer diarrhœa (epidemic or zymotic enteritis) and the latter occurring as a complication of another infection, particularly measles and broncho-pneumonia. Summer diarrhœa affected particularly artificially fed infants of the poorer classes during the summer or autumn months; four factors—artificial feeding, infancy, unhygienic surroundings, and high temperature—combined to produce the disease. A raised external or internal temperature affected adversely gastric and intestinal secretions, so that in infants the initially low gastric acidity tended to be neutralised by the highly buffered cow's milk and the sterilising mechanism in the stomach and upper intestine was interfered with. The consequent ascent of coliform organisms from the lower bowel to this virgin soil, plus possibly bacterial infection of food, prevented proper digestion, and the general irritative action produced a gastro-enteritis. The use of low-buffered acidified foods would probably help both in the prevention and treatment of this type of enteritis. It was well to remember that breast-fed infants were practically immune.

Dr. M. **MITMAN** (Eastern Hospital, L.C.C.) said that diarrhœa was the pivotal symptom of enteral infections in children. Two other groups of alimentary disorders in which diarrhœa was a feature had to be excluded: those due to parenteral infections and those caused by digestive disorders. Distinction was not always easy. In some enteral infections, such as the enteric fevers and the dysenteries, the causative organisms were known. In others various organisms had been described but their rôle was in dispute. There remained a mixed group (gastro-enteritis, summer diarrhœa, cholera infantum, infectious enteritis, winter vomiting, alimentary toxicosis, &c.) in which specific micro-organisms could not be implicated but which behaved in all respects like transmissible diseases. There were pædiatrists who denied that infection played a primary part in these cases, but the evidence in favour of an infective origin was strong. Infections of known causation could usually be differentiated on clinical, bacteriological, and serological grounds. Clinical diagnosis was usually most difficult in infants, in whom the typical syndromes might be replaced by a gastro enteritis Sonne dysentery and paratyphoid fever were examples The diagnosis of parenteral infections depended upon the detection of the focus In the remaining diarrhœas differentiation was difficult in the absence of bacteriological and serological aids Some assistance could be obtained from variations in the clinical syndromes, from biochemical changes in the stools, from the season of the year and from involvement of other systems such as the respiratory tract and the middle ear Changes however were not sufficiently specific to be an accurate guide to classification.

The practice at the Eastern Hospital was to segregate the dysenteries (almost exclusively Sonne) and congregate the remaining cases in an enteritis ward This heterogeneous group had a fatality rate ten times as great as the dysenteries If as seemed probable these cases of enteritis included a number of infections of unknown causation, it was not justifiable to nurse them side by side in an open ward It was also illogical to segregate cases of dysentery with a relatively low fatality rate and leave other infections with a higher rate, together It was in fact much more important to remove from an open ward a case of diarrhœa with a negative dysentery report than one with a positive finding In the mixed group the mode of transmission was still uncertain Infection by ingestion was probably the commonest method but there was evidence that some particularly those occurring in winter were conveyed by droplets. This might explain the *frequency of middle-ear and respiratory infections in some* outbreaks of diarrhœa

It was proposed in future to treat all cases at the Eastern Hospital by a combined cell and diet kitchen technique Every case of enteritis whether primary or secondary to other infections such as measles and whooping-cough was to be *treated as infectious* and each case was to be considered as a separate infection from every other case Patients were to be nursed in separate cells Feeds were to be prepared in a special milk room by a gowned masked, and gloved nurse carrying out an aseptic technique After use bottles and teats were to be sterilised in a special steriliser in the kitchen and passed through a hatch into a drying chamber in the milk room. Scrupulous care was to be taken in the disposal of excreta Destructible squares were to be used where possible Sluicing of foul linen was to be avoided as far as possible; if unavoidable the nurse was to wear a rubber apron galoshes and gloves, and forbidden to enter the milk room By these measures it was hoped to minimise cross infection in enteritis.

Dr **David Haler** (London) said the classification he favoured was a clinico pathological grouping based upon the clinical examination of the child and a careful bacteriological examination of the stool

Group 1 with a high mortality showing no abnormality in stools except for their frequency The child was over whelmed by a severe toxæmia or perhaps septicæmia. The normal ratio of coliform to lactic acid bacilli was maintained in direct films. Cultures showed no abnormality

Group 2 with rather a lower mortality associated with focal sepsis and in these cases the disease was not so acute The cardinal finding was a reduction in the lactic acid to coliform bacillary ratio

Group 3 was a complex *one* associated with various organisms actually attacking the gut The organisms might be cocci or bacilli and comprised the usual enteral infections. Pus and blood were usually *present* in the stool

Group 4 was associated with a depression of general bodily resistance by other diseases and invasion of the gut by proteiform bacilli

The prognosis in Group 3 was relatively good; in Group 4 it depended on the associated disease Groups 1 and 2 were truly parenteral Group 3 and its subdivisions were enteral. Group 4 was secondarily enteral in character He concluded by emphasising the extremely high infectivity of the true dysenteries and their relatively low mortality

Dr **A Joe** (North Western Hospital, L C C) said he was interested to learn that Dr Mitman's precautions against the spread of intestinal infection (since he proposed to employ cell isolation) included those designed to exclude droplet infection Those present including himself would probably be loth to give up the hypothesis of manual transmission as satisfactorily accounting for spread in the preponderance of cases, but the work of W F Wells in America if confirmed would reopen the whole question of air borne infection Under experimental conditions Wells had shown that intestinal organisms had maintained their viability in air currents when attached to droplet nuclei and these might account for such a rapidly spreading outbreak as described in Bristol by Parry and Peters He himself had had one such experience but had been unable to exclude the possibility of food contamination by a wardmaid who had had an acute attack of diarrhœa three weeks prior to the outbreak which was not disclosed until a rapid succession of cases of Sonne dysentery caused the fullest inquiries to be made

Dr **J S Anderson** (Grove Hospital, L C C) agreed with Dr Mitman that as far as the infectious diseases hospitals were concerned diarrhœa was either infectious or not As it was sometimes impossible to differentiate every case of diarrhœa should be regarded as potentially infectious and isolated He referred to an outbreak of twelve cases of Sonne dysentery among which was a child ten months old, to whom attention was drawn on the occurrence of one green motion without other symptoms That green motion on culture was found to contain *B dysenteriæ* Sonne He thought more attention should be paid to the anal toilet in children's wards and that members of the nursing staff should report at once even the slightest attacks of diarrhœa in themselves

Dr **D S Sutherland** (Manchester) referred to cases of recurrent diarrhœa of dysenteric character admitted for investigation to a base hospital in Northern France during the latter part of the war Other than the cases of bacillary dysentery which could be attributed to an organism of Shiga Flexner or Morgan type or cases attributable to *Entamœba histolytica* many were found to be due to amœbic infection The pathological report in many of these indicated the cause as *Entamœba coli* while other cases were reported as due to *Balantidium* (*Paramœcium*) *coli* and *Giardia* (*Lamblia*) *intestinalis* Amœbæ might he thought be the cause of recurrent diarrhœa in this country

A mild outbreak of dysentery occurred in October-December 1935 in the wards of Monsall Hospital mainly confined to two wards of the 45 cases 41 were patients and 4 nurses The disease was highly infectious but mild with no deaths The characteristic feature was frequent relaxed offensive stools In 31 cases mucus was present in the fæces and in 18 of these blood was present in streaks; there was no altered blood; In 9 cases the stools were green In 22 cases there was a rise of temperature during the attack, the rise occurring on a few occasions before any change in the stools was noticed and in others after the diarrhœa commenced The temperature was raised in most cases for one day only, in 2 cases for five and six days, the rise was over 100° F in 5 of the 22 cases, 2 reaching 104° In 4 cases only was there abdominal pain, in no case was there vomiting The organisms isolated in the cases examined were of the Sonne type The source of the outbreak was not determined

In searching for the source of such outbreaks he thought the organisation of the hospital kitchen should be inquired into Dust originating from earth attached to unprepared vegetables might readily infect the food supply, and he would like to see the preparation of food, particularly vegetables, completely separated from its cooking Minced meat should be entirely used on the day of cooking, what was left over might readily harbour and grow organisms implanted by dust

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this institution on Feb 4th, with Prof R E Kelly, the president, in the chair, a paper on the

Medical Treatment of Hepatitis and Cholecystitis

was read by Prof J W McNee (Glasgow) He began by speaking of the definition of hepatitis, describing it as the response of the liver to injury Apart from abnormalities and tumours, most of the hepatic disorders described in text books under separate names could be united as examples of hepatitis The pathological process varied from cloudy swelling in fevers, through fatty infiltration or degeneration to the most severe hepatitis of all —necrosis of the liver cells or of large areas of liver tissue, the so called acute necrosis (yellow atrophy) of the liver Even the condition commonly known as cirrhosis of the liver was readily included as "chronic interstitial hepatitis," analogous with chronic interstitial nephritis Various factors influenced the effects of hepatitis—whether this was acute or chronic, temporary or severe The two most important were, first, the great excess of liver tissue over normal needs, and, secondly, the amazing power of regeneration of liver cells The essential point in the treatment of all forms of hepatitis was to give the damaged liver the best chance to regenerate, and glucose was the only support we could offer it

Turning to cholecystitis, Prof McNee remarked on its commonness, and on its infrequent diagnosis in its earliest stages when medical treatment was of avail The possibility of catarrhal cholecystitis must be considered in every case of indigestion not due to obvious organic disease of the stomach such as ulcer and not responding to simple treatment The suspicion of cholecystitis was increased if flatulence was a notable symptom From the standpoint of treatment it was important to know whether the infection was deep in the wall of the gall bladder only, as surgeons suggested, or in its fluid contents If it was in the wall antiseptics excreted in the bile would be unlikely to have much therapeutic effect, and it would be preferable to use some remedy acting through the blood In the diagnosis of catarrhal cholecystitis Prof McNee attached great importance to the use of the duodenal tube to obtain samples of bile for microscopic examination

Dr N B Capon referred to some of the forms of hepatitis seen in childhood, and supported the use of glucose in these cases, especially when combined with insulin

Dr R E Roberts, while agreeing with Prof McNee that the information obtainable from cholecystography is sometimes unreliable, held that the help obtained in the majority of cases is more exact than that available from any other source In a normally functioning gall bladder or in a frankly non filling gall bladder, the presumptive evidence in favour of normality or pathology of the gall bladder was very strong In the case of opaque gall stones direct radiography might suffice, but with non-opaque gall stones cholecystography might provide incontrovertible evidence There was, however, a type of gall bladder in which the evidence given by oral cholecystography was open to criticism—namely, the type which fills well, empties normally, but throughout the examination shows a shadow of subnormal density It was not at all clear whether the radiologist ought to regard such appearances as evidence of subnormal concentration and an indication of cholecystitis, or whether it was merely an indication of something amiss with the absorption of the dye from the bowel and with its subsequent excretion by the liver So many factors had to be considered in the transit of the dye from the mouth to the gall bladder that many possibilities in the nature of faulty absorption or elimination must if possible be excluded before the diagnosis of cholecystitis was made Such exclusion seemed at present impossible without resort to intravenous cholecystography

Prof Henry Cohen, in acknowledging the diagnostic value of duodenal intubation, nevertheless emphasised the importance of correlating the evidence it afforded with that derived from clinical and radiological investigation Cholecystitis might be the sole manifestation of such lesions as gall stones or neoplasms in the biliary tract, and its adequate treatment depended on a recognition of the underlying causative factors Of the value of cholecystography he spoke feelingly, for it was in the Liverpool Medical Institution that he showed, with Dr R E Roberts, the first series of cholecystograms taken in England But as a clinician he was alive to its dangers Pain in the right upper quadrant of the abdomen in the days before cholecystography was an exercise in careful anamnesis Now too frequently the mere hint of discomfort in this area associated with slight flatulence led to a radiological examination of the gall bladder and thence to cholecystectomy if gall stones were revealed But gall-stones were not uncommonly symptomless and their association with certain symptoms might be accidental and not causal He had seen the gall bladder and its contained stones removed for pain which later proved to be due to spinal tumour, caries, carcinoma of the lung, myocardial ischæmia, right pyelectasis, and other lesions which ought to have been recognised He considered Prof McNee's analogy between liver and kidney infections most helpful and proposed that it should be carried a step further Might it not be that some cases of cholangitis and cholecystitis occurred independently of hepatitis, although the liver had excreted the infecting organism, might not the infection persist in the gall bladder after the organism had ceased to be excreted by the liver? If so, it was to be expected that some cases of gall stones with associated cholecystitis would show hepatitis whilst others would not The hypercholesterinæmia of certain types of nephritis did not predispose to gall-stones The medical treatment of established cholecystitis apart from the mild catarrhal types which might resolve without any treatment was still on the whole disappointing Judging by cholecystography appropriate foods caused biliary drainage as efficiently as concentrated solutions of magnesium sulphate Massive doses of hexamine often produced gastric and urinary discomforts whatever dose of alkalis was given with them. Olive oil and Decholin allayed symptoms. Prof. Cohen doubted whether removal of the gall bladder as a suspected source of focal sepsis was ever justified unless the gall bladder itself was giving rise to symptoms which even in the absence of general toxic disturbances were severe enough to justify its removal There was a danger in some centres of the gall bladder becoming Bernard Shaw s nuciform sac.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At a clinical meeting of this society held in Manchester on Jan. 22nd, Dr J W Bride (Manchester) the president, being in the chair a preliminary account of the working of the

Hormone Clinic at St Mary s Hospital

was given by Dr J W A. Hunter (Manchester) who began by expressing his indebtedness to his colleagues at the hospital for permission to record the results. It was premature he said to draw any conclusions but he hoped the results might be helpful to those who were considering setting up a similar clinic During the first six months some 90 cases came to the clinic most of whom being referred there from the out-patient departments Some were deemed unsuitable for treatment some had only commenced treatment in the latter weeks but there remained 52 cases that had received sufficient treatment to justify a criticism of the results The cases treated were as follows —

Secondary amenorrhœa	20
Sterility dysmenorrhœa	6
Hypomenorrhœa	11
Menorrhagia of puberty	4
Pruritus vulvæ	5
Repeated miscarriage	3
Menorrhagia	2
Primary amenorrhœa	1

Of the 20 cases of secondary amenorrhœa 14 were temporarily cured that is to say the periods had returned after treatment by varying amounts of intramuscular œstrin; but in only 2 of these cases had the restoration of function been permanent In 4 cases treatment in large doses had failed to restore the menstrual flow a result at variance with those recorded by Kaufmann In 5 cases of pruritus vulvæ associated with the menopause 4 had been definitely cured by œstrin therapy In 4 cases of adolescent menorrhagia 3 had been cured by treatment with ultramuscular progestin In 17 cases of scanty menstruation associated with dysmenorrhœa or sterility 11 had shown no improvement with prolonged treatment and in 6 there had been some slight increase in the flow In no instance had the dysmenorrhœa been affected *and no case of sterility* had become pregnant Three cases of repeated miscarriage had gone to term with progestin treatment combined with the administration of vitamin E. One case of primary amenorrhœa had been treated with large doses of œstrin but with no effect but 2 cases of menorrhagia in patients *thirty* years of age had much improved under progestin treatment

The preparations employed were supplied by Schering In the cases of amenorrhœa he had used progynon B oleosum *forte* The smallest dosage necessary in any case to produce a menstrual flow was 300 000 units the largest amount required in any one case was 1 250 000 units In menorrhagia of puberty the average monthly dose found necessary to control the menstrual flow was 10 international units. Most of the treatment had been replacement therapy little had been done in the direction of activating therapy using the pituitary hormones As regards permanency the results had been disappointing with the exception of menopausal pruritus, other climacteric symptoms and adolescent menorrhagia

The chief criticism of such a clinic Dr Hunter said was that one tended to be working in the dark with no certain knowledge of the underlying conditions Cases might be primary ovarian, or primarily due to pituitary deficiency but apart from clinical signs we had no methods of establishing a diagnosis He thought perhaps some help could be obtained by routine estimations of the basal metabolic rate and also perhaps of the blood hormone content For this a biochemical laboratory and a skilled staff would be necessary and it seemed to him that future progress was only possible along these lines.

The President expressed his interest in the results — Mr J E Stacey (Sheffield) asked whether Dr Hunter had discovered anything about what time in the cycle *these* hormones should be used Personally he had seen good results in pruritus vulvæ. He thought that many of the effects obtained by substitute therapy were got as the result of psychological influences —Dr F H Lacey (Manchester) asked whether Dr Hunter had ever compared the results in repeated miscarriages with those obtained from antisyphilitic treatment. His results in the latter had been very good and he used the treatment whether the Wassermann reaction was positive or not

In reply Dr Hunter said that in timing the treatment he had used Kaufmann s table but unfortunately they had not been able to afford the huge doses used by Kaufmann. In his opinion menstruation tended to carry on so long as there was any hormone secreted at all. He thought that secondary amenorrhœa was due to a sudden cessation of hormone production His series of repeated miscarriages had not had any history of syphilis In most of his cases there had been a history of scanty menstruation He believed that diet was a very important factor

Pseudomucinous Ovarian Cyst with Cystic Endometrium

Prof. D Dougal (Manchester) said that in the last few years he had met three cases with cystic changes in the endometrium associated with a pseudomucinous ovarian tumour The ages were 58 60 and 61 The first patient was single but the others were married and had borne children Each had a large abdominal cystic tumour and complained of a blood stained vaginal discharge In each panhysterectomy was performed and the tumour was a pseudomucinous cyst-adenoma In one patient an inoperable carcinoma of the descending colon was also present On opening each uterus after operation a quantity of blood-stained pseudomucinous material was found on the endometrium—raised up to form a number of thin walled cyst In two cases this was also found in the cervix

REVIEWS AND NOTICES OF BOOKS

Trachoma

By A F MacCallan, C B E, M D, F R C S, Surgeon in Charge of Out-patients, Westminster Hospital, London, formerly Director of the Egyptian Government Ophthalmic Hospitals Embodying a Hunterian Lecture at the Royal College of Surgeons of England, 1936 London Butterworth and Co, Ltd 1936 Pp 225 21s

Fifty years ago any worker at Moorfields Eye Hospital would have been confronted with many cases of this disease, for most of the infected immigrants into East London from the affected districts of Europe at that time found their way there, but to the younger generation of ophthalmologists in England the disease is practically unknown Only among those ophthalmic surgeons who have undertaken hospital duties in Egypt, Palestine, or the Far East are British "trachomatologists" now to be found

The natural evolution of trachoma was first described by MacCallan in 1905, when he was working in Egypt, as occurring in four stages These stages are now generally accepted and together with certain varieties which occur in Stage II are well described and illustrated with coloured plates in this book The early diagnosis of the disease depends in difficult cases on the detection of pannus This, which in the early days was apt to be regarded as only a later complication due to mechanical contagion from the heavily infected upper lid to the cornea, is described by MacCallan as a sign invariably present even in the first and second stages Unfortunately its presence or absence in early cases can only be verified by the corneal loupe or the corneal microscope with slit-lamp in skilled hands, this examination takes some time, so that where mass infection has to be investigated the method is impracticable It is, however, the only reliable criterion according to MacCallan, who attributes the infection of the cornea not to direct contagion but to slow and inevitable advance from the original site of infection in the conjunctiva of the upper lid As to treatment, detailed instructions are given, varying according to the stage and particular variety of the disease These display a great advance over the days when the almost universal panacea was the drastic and cruel copper sulphate stick

As to the pathology of the disease, a vast amount has of late years been published in support or in criticism of two theories of causation one that it is to be found in the so called Halberstädter Prowazek Körperchen (H P K) structures found to be included in the epithelial cells, the other and more recent one that it is due to an organism known as *Bacterium granulosis* discovered by the Japanese bacteriologist Noguchi Neither of these theories has been found to be capable of proof and knowledge of the ætiology of the disease remains incomplete

The latter half of this work is occupied with the epidemiology of the disease, its history, and a discussion of the prophylactic measures best adopted on the one hand for individuals living in infected areas and on the other to the schools &c, in areas where the disease has already or has always been endemic For a great part of the world the disease appears to be a universal scourge and there appear to be no natural conditions, either geographical or racial which by themselves can render any area immune At the same time no student of this book can regard the fight against trachoma as hopeless Great improvement has already followed from the systematic prosecution of prophylaxis under scientific guidance in Egypt, and a victory on a smaller scale is the elimination of the disease from our own poor law schools in England since segregation was adopted

Pathological Physiology and Clinical Description of the Anæmias

By William Bosworth Castle, M.D, S M., Associate Professor of Medicine, Harvard University; and George Richards Minot, M.D, S D, F R C P Edin., Professor of Medicine, Harvard University Edited by Henry A Christian, A.M., M D, LL D, Sc.D, Hersey Professor of the Theory and Practice of Physic, Harvard University London Humphrey Milford, Oxford University Press 1936 Pp 205 15s

The pioneer work of George R Minot and William B Castle on Addisonian pernicious anæmia laid the foundation for an entirely new conception of the ætiology of a wide group of conditions associated with abnormalities of the hæmopoietic system It is therefore fitting that their review of the problem of the cause and treatment of the anæmias should be reprinted from the Oxford Loose Leaf Medicine in a form easily available to workers in medicine and allied sciences The short introductory chapter on the physiology of the erythron contains a stimulating account of the processes of blood production and blood destruction It illustrates well how much can be learnt of the processes of normal physiology by the exact quantitative study of pathological conditions as seen in clinical practice The hospital ward, in the hands of men like Minot and Castle, becomes a place in which as exact a science is practised as in the laboratory of the physicist or chemist In this monograph the authors give a concise description of diagnostic technical methods and an analysis of the significance of the reticulocyte response, but emphasise that "it is important to recognise clearly that meticulous descriptions of the peripheral blood in themselves often signify little without correlation with clinical syndromes and in particular with the chronology of proceedings symptoms and therapy"

The anæmias are classified on an ætiological basis as far as possible Congenital anæmias of infants, Cooley's erythroblastic anæmia, aplastic anæmia, the macrocytic anæmia of liver disease, and splenic anæmia are grouped together as idiopathic Macrocytic anæmia associated with liver disease and achrestic anæmia, they suggest, are not due to a derangement of the internal metabolism of the P A. principle, as is usually believed, but are dependent upon some, at present unexplained, depression of erythropoiesis Myelophthisic or leuco erythroblastic anæmia is regarded as due to mechanical interference with the blood forming organs The exposition of general principles of treatment is admirable in its clarity and the necessity of making a correct diagnosis before the blood picture is obscured by indiscriminate therapy is emphasised. Specific treatment is discussed under the headings blood transfusion, abolition of blood loss and increased blood destruction, administration of essential erythropoietic factors, elimination of toxic agents, X ray and arsenic treatment, and splenectomy Apart from general principles notes are also given on the special treatment of certain types of anæmia There is an excellent bibliography but a fuller index would have been helpful, for it is book that will be used for constant reference as ell as read as a whole for the picture it gives of he principles underlying the modern diagnosis nd treatment of the anæmias.

The 1936 Year Book of the Eye, Ear, Nose, and Throat

By E V L BROWN MD Professor LOUIS BOTHMAN MD Assistant Professor of Ophthalmology GEORGE E SHAMBAUGH MD Clinical Professor Emeritus ELMER W HAGENS MD Assistant Clinical Professor and GEORGE E SHAMBAUGH, Jun MD Clinical Instructor in Otolaryngology University of Chicago Chicago: The Year Book Publishers London: H K Lewis and Co Ltd Pp 632 10*s* 6*d*

THIS issue consists of abstracts from the current literature excellently edited and well written by the same authorities who have undertaken the task in recent years Editorial comment is not withheld and critical attention is given to therapeutic claims For example the treatment of otosclerosis by local injection of thyroxine is discussed in connexion with the late Dr Albert Gray s original claim to have obtained seven cases of improved hearing among fourteen patients by the use of this method The editors have tried the method in a few cases using the audiometer to test the hearing and have found in no instance any significant alteration in the hearing If the audiometer tests are made by a technician the results are comparatively free from errors which are almost bound to arise with the whisper test. They say *that with the slightest* encouragement each patient would have declared that the hearing seemed improved and they believe that it is this psychological element in deafness which is responsible for the continued vogue of all kinds of methods in the treatment of otosclerosis In this connexion they quote a report by H C Ballenger and B A Patterson who treated 25 partially deaf patients with an instrument similar to but apparently not identical with that of Zünd Burguet using the 2 A audiometer to follow the acuity of hearing. In only five patients was there any improvement: in two of these it was so slight as to fall within the normal range of variation in one treatment began three weeks after an acute suppuration and the remaining two were cases of chronic catarrhal otitis in which spontaneous improvement is more likely to occur than in otosclerosis or nerve deafness A number of abstracts are given concerning petrositis which has recently attracted much attention

Much interesting work has been published during the year under review on diseases of the nose and throat, including Henri Coutard s recent report on the results of treatment of cancers of the tonsil pharynx and larynx by X rays according to his own method. The best five year results of 32 per cent were obtained in the tonsillar region tumours of the larynx gave 26 per cent and of the hypopharynx 11 per cent. The editors point out that a new era has been opened up by Coutard s work five-year cures are being obtained with gratifying frequency in cases previously deemed hopeless the indications for surgery are being narrowed to intrinsic carcinomas of the larynx and to a few early lesions el ewhere

With regard to diseases of the eye a useful collection of abstracts on glaucoma includes a long illustrated article by C Berens describing his operation of iridocorneosclerotomy for the relief of this disease In a study of optic nerve atrophy in relation to pituitary tumour F Fischer finds temporal pallor of the disc the most frequently observed alteration in the nerve head; he also finds that this pallor remains unchanged no matter how good are the results of operation an observation not in accord with the findings of other authors A number of rare neoplasms of the choroid are described and E Hesse reports a favourable result in the treatment of methyl-alcohol amblyopia by repeated lumbar puncture as a result of prohibition this affection was far commoner a few years ago in the United States than in England.

The book is provided with a good index and is indispensable to those who want to keep track of progress in these specialties

Chronic Indigestion

By C J TIDMARSH MA MD FRCP (C) Associate in Medicine Royal Victoria Hospital Montreal. London: Longmans, Green and Co Ltd 1936 Pp 143 6*s*

THIS small handbook is described on its yellow and red wrapper as "a layman s handbook above the title is written with a large question mark Are you one of the 10 per cent ? and beneath is the alarming announcement ten per cent of all people are affected by ulcers of the stomach. Whether such a statement is precisely accurate is of less importance than the effect such information may produce upon the reader Books designed as this one is for both patient and physician have the object *of helping the patient to take an intelligent* interest in his case, and thus to secure his coöperation but they tend as a whole rather to encourage a morbid preoccupation with symptoms Peptic ulcer is however one of the conditions in which the patient s coöperation is all important and where the physician feels the need of written instruction to supplement his verbal ones Dr Tidmarsh s little book shorn of its cover should serve the purpose His teaching is sound and he gives useful advice as well as timely warnings against incautious treatment Physicians may themselves find a use for this book as a summary of the problems of chronic indigestion. The chapters on nervous indigestion and the unstable colon are especially good.

Hay Fever

With Special Reference to Treatment by Intranasal Ionisation. By CLIVE SHIELDS B.M. B Ch Oxon. Clinical Assistant Physiotherapy Department, St. George s Hospital. London: Humphrey Milford Oxford University Press 1937 Pp 57 7*s* 6*d*

IN this little book the author argues the superiority of intranasal zinc ionisation over other methods in use for the treatment of hay fever He does not describe the technique of desensitisation by pollen extracts he does not mention the galvanocautery and he condemns without reserve all kinds of palliative local applications Records have been kept of the previous treatment received by his patients from which Dr Shields has drawn up a table showing that 82 per cent of those who had had desensitising injections and 100 per cent of those treated by cauterisation had experienced no relief It is *not* surprising that a large proportion of his patients are people who had failed to get relief from other methods the figures are of no value in assessing the *results of these methods* The technique recommended is similar to that used by other workers three treatments of 8–10 mins at weekly intervals, with a 2 per cent solution of zinc sulphate, and a maximum current of 3 milliamperes for the first treatment, 7 milliamperes for the second, and 15 milliamperes for the third Dr Shields very properly lays stress on the importance of careful application of the zinc moistened gauze to the upper and back part of the nares, and on the avoidance of necrosis by the use of small doses of current He says he obtains 90 to 100 per cent of relief in 93 per cent of cases, whereas other observers have been content to claim 66 to 80 per cent The method is a useful one, and it is probable that those who have had bad results from it have employed a faulty technique or applied the packing unskilfully But the value of this book is impaired by over emphasis on the merits of one form of treatment to the exclusion of all others

Synopsis of Diseases of the Heart and Arteries

By GEORGE R HERRMANN, M.D , Ph D , Professor of Clinical Medicine, University of Texas London Henry Kimpton 1936 Pp 344 17*s* 6*d*

THE systematic consideration of heart disease in this book opens with a discussion of the study of a patient suspected of heart disease This section, specially in its dealing with symptomatology, is one of the best in the book, although the list of possible findings in examination is rather too exhaustive In classifying morbid conditions of the heart the outlines approved by the American Heart Association have been followed, and diagnosis is considered from ætiological, structural, and functional standpoints in turn When it is remembered that many patients seeking advice for troubles apparently cardiac have no disease but only a functional disturbance of the heart or its nervous mechanism, it is surprising that more systematic consideration is not given to this group, which includes the very common left mammary pain, nervous tachycardia, and suspirious as well as the effort syndrome Dr Herrmann has compressed a great deal of information into a relatively small space Many useful diagrams and charts have been included, together with good photographs of morbid anatomy and microphotographs Much attention to important detail has been given in therapeutics and management in heart disease and failure But the volume is hardly as comprehensive as the title would suggest because the discussion of peripheral vascular disease occupies only nine pages The value of future editions would be much enhanced by an elementary treatment of the symptoms and signs of the common forms of arterial disease , a precise account of the reactive hyperæmia test, for example, is of far greater importance than a picture of the Tycos Dermatherm

Diseases of the Nails

By V PARDO CASTELLO, M D , formerly Assistant Professor of Dermatology University of Havana London Baillière, Tindall and Cox 1936 Pp 178 16*s*

THERE will be no two opinions on the merits of this little volume, and few will read it without profit to themselves and a measure of gratitude to a painstaking and able writer The subject of this book, owing perhaps to the poverty of our therapeutic armamentarium, has been neglected too long, and even the trained dermatologist, "often at a loss to make a diagnosis," as Howard Fox remarks in his foreword, has been apt to underestimate its importance, both in his clinic and in the lecture room A further obstacle to study is the involved nomenclature, mainly Greek in its origin, and therefore antagonistic to all but those of us who succeeded in reaching the "Vth form on the classical side" Dr Pardo Castello will be found to have made things very easy for the reader , he has a lucid and most attractive style Two simple diagrams clarify in the ungual anatomy what has always appeared rather complicated. These diagrams should be carefully studied and memorised, or redrawn from memory, because constant reference to the parts depicted—i.e , nail bed, matrix, nail root, lunula, and so forth—is made in the seven succeeding chapters These deal with affections peculiar to the nails, dystrophies, congenital affections, the effects of cutaneous and systemic diseases, occupations, and poisons An extensive and carefully selected bibliography will stimulate the interested reader to further study or research, and the 94 clinical illustrations will be found invaluable The treatment of nail diseases by X rays is considered specially in a final chapter A word of warning is appropriate here The value of radiotherapy is considerable, but in the hands of the inexpert it has inflicted irreparable damage in just this type of case

A Textbook of Physiology

For Medical Students and Physicians Thirteenth edition By WILLIAM H HOWELL, Ph D , M.D , Sc D , LL D , Emeritus Professor of Physiology in the Johns Hopkins University, Baltimore London and Philadelphia W B Saunders and Co , Ltd 1936 Pp 1150 30*s*

THE general scope and character of this excellent text-book were recalled in these columns when the twelfth edition appeared in 1934. The thirteenth edition bears the brief legend "thoroughly revised," and has a preface which does not enlarge upon this text except in an impersonal way The author disdains to act as his own commercial traveller, or to display self pity at the magnitude of his task, which has been conscientiously performed The changes which have taken place in our knowledge, for instance, of the vitamins, the hormones, the autonomic nervous system, and the cerebrum, all find a place, and the sections describing them seem to fit naturally into the text Less space is devoted to the properties of reflexes and a little more to the anatomy of the nervous system than is customary, and the chemistry of the foodstuffs needs supplementing by reference to a biochemical text book, but these can hardly be called defects One of the main features of the book is its convenient size , no part of the subject is neglected and the balance has been maintained with skill The style is straightforward and the exposition clear , the size of the book prohibits very detailed discussion, but accuracy is not sacrificed to clearness *It must be borne in mind by the student that the text book comes from the other side of the Atlantic, and he may find the emphasis and arrangement unfamiliar in one or two places* But it contains practically all he requires in a small compass, and avoids many of the usual defects of a short book *It is adequately but not profusely illustrated, well indexed, and has a useful detailed table of contents showing the subdivisions of the chapters and the pages on which they occur*

THE LANCET

LONDON SATURDAY FEBRUARY 20 1937

THE ADOLESCENT IN INDUSTRY

ANY medical man who was fortunate enough to hear the two-days' debate in the House of Commons on the second reading of the Factories Bill must have been impressed by the desire in all parts of the House to ensure the healthiness of industrial life, and especially to protect the worker of tender age. But he could not fail to have been also impressed by the scarcity of scientific or medical data on which to base a reasoned judgment on the proposals before the House. What is the effect upon the adolescent of long hours or of night-work? What are the precise conditions under which young persons of either sex can play their part in industrial life without risk to their present health or future development? It must be admitted that scientific medicine can give no categoric reply to these questions. They cannot be answered in terms of established disease and defect, and despite the pioneer work of the Industrial Health Research Board and of the London School of Hygiene a start has hardly been made in the biology of healthy industry, for there has been next to no opportunity for continuous medical supervision from the inside. And in any case the problems of industrial health are economic as well as medical. Nevertheless there are biological principles known to medicine which can only be neglected at our peril. We are aiming at a healthy industrial life for the adolescents, and the *hygienic conscience* cannot be stifled by the lack of evidence that illness is being caused by this or that process or time-table. If the Factories Bill does nothing more than establish conditions which will not cause manifest disease, most of the effort expended in the campaign for physical fitness and much of the work of the Ministry of Health and the Board of Education will be sterilised.

There are at present some 600,000 young persons of 14–18 years of age working in factories, not counting those in unregulated employments. Under the new Bill, as drafted, boys and girls under 16 years of age may work 48 hours a week but not longer; furthermore the Secretary of State can by regulation prohibit or limit overtime for juveniles of 16–18 "in any process in which overtime can be shown to be prejudicial to their health." We shall all agree that these provisions are an advance on existing practice, but medical men will ask whether, except in rare and extreme cases, it will be possible to demonstrate the "prejudice to health" which overtime or night-work may cause. Neither young workers nor, as a rule, their parents desire that overtime should cease; experience shows that the incentive of the added pocket money is apt to outweigh all other considerations. Any ill effect which long hours or lack of sleep may have upon the health of these juveniles will not become apparent until after they have become adults and the law has ceased to apply to them—when it will be too late to amend the error. For example, BRADFORD HILL in his studies of sickness amongst operatives in Lancashire spinning mills says: "There is no evidence of an excess of respiratory illness amongst younger workers who have only worked under modern conditions (except perhaps in the higher rates of single women 25–29)," but he adds, "this is not conclusive that modern conditions do not cause respiratory illness, since it may be that some years' exposure is necessary before the effect of the environment will be shown in absence from work due to illness." Again R. M. FLEMING, speaking of the adverse influence of certain environmental conditions upon the physical and psychological development of adolescents, says: "The adverse effect of an improper midday meal was not immediately apparent, but its effects were cumulatively felt, so that a second year of such conditions reflected itself in stunted growth." It has been urged that overtime or night work need not affect nutrition. Medical experience suggests that they do affect nutrition in a variety of ways, and in any case nutrition is only one of the many environmental and physiological conditions which together determine the adolescent's health and development. School medical officers have observed and recorded the harm done by lack of sleep upon growing children. Wise parents and family doctors are very familiar with them. If it is asserted that it is harmless for juveniles of 16–18 to work at night or to exceed the usual working hours, medical men will be cautious of agreeing with the assertion. It is true enough that the effects may be difficult to demonstrate. It is hard to tell what the young person would have been like in a different environment—although comparison may fairly be made with those in public schools or with continuation class groups—and the effects may not be manifest until early manhood. The years 16–18 are an important part of the formative period of adolescence; they include the latter end of the "second period" of rapid growth which FLEMING has so carefully studied. Mistakes in this period are irretrievable.

If it is really necessary that young persons should work either at night or overtime it appears that there is less danger in allowing *young girls* (between the ages of 16–18) to do this kind of work than in allowing youths of the same age to do it. At the age of 14–16 girls, as MORGAN ROCH of Harvard has pointed out, are more mature than boys. From 16–18 years, and over, most youths are growing with greater rapidity; for girls the period 11–16 years is determinant. Biologists like W. VON GONZENBACH of Zurich have emphasised the necessity of minimising the external life-changes during the pressure of internal change which takes place during puberty if physical or mental disturbance is to be avoided. "To postpone to 15 years the entry into industry is not," he says, sentimental philanthropy but biologically well-founded economics These are a few of the medico-biological considerations to be taken into account by legislators There remains the recent sinister increase in juvenile accidents, which suggests that some cumulative strain is already in action, and the admitted strain which even normal hours of work may throw upon the young persons in occupations where there are loads to be lifted And we are unaware of any systematic research to assess the effects of two- or three shift systems upon the development of young people

The positive evidence of the *good* effects of properly regulated employment for the age group 16–18 should not be forgotten, and it is undoubtedly possible to combine wage earning with education in a way that fulfils the chief needs of many boys and girls The reports of the continuation schools at Rugby and York and Birmingham could be re read with advantage But it seems to us that anyone who employs young people must be able to show that the conditions are reasonable and we should regard night-work as guilty until proved innocent rather than innocent till proved guilty Whatever may be the economic pressure on juveniles for night-work, for overtime, or for two shift systems, it must be resisted in view of the medical evidence—even if this does not amount to proof—that such kinds of work between the ages 16–18 are biologically unsound They must be unsound, because they are likely to interfere with the normal processes of growth Happily it is not for the medical profession to decide between the rival claims of economics and health, its task is to state the truth so far as it is able to do so, and on the evidence available to it On this evidence, as it at present stands, overtime and night-work are not to be tolerated for adolescents, and we hope that Parliament may be persuaded to amend the present Bill so that, for those under 18 years old, the 48 hour week is exchanged for a maximum of 40 hours employment with 7–8 hours' education and recreation

VASCULAR SPASM AND ASTHMA

THE distribution and function of the bronchial arteries has long been a matter of interest to Prof I DE BURGH DALY and his colleagues They were led to its study in their search for the method of vascular adjustment in the lungs, the contractility or otherwise of the pulmonary arterioles and capillaries being in dispute For practical reasons, indisputable information about the behaviour of the pulmonary vessels can be obtained only from a preparation of isolated lungs, and Prof DALY felt that preparations of this sort in the past had perhaps lacked something vital in the shape of a blood supply through the bronchial arteries An analogy would be a preparation of the surviving heart in which a perfusion of the coronary circulation was omitted Perfusion of the bronchial arteries as well as the pulmonary did, in fact, reopen the whole question of vascular control in the lungs The pulmonary circulation was now found responsive to nerve stimulation, whereas before it had been inert Vasoconstriction and vasodilatation were readily demonstrable This was attributed to survival in the lungs of nerves which in previous experiments had quickly perished from ischæmia of the tissues in which they were embedded Since histological and anatomical studies show that the bronchial vascular system supplies every tissue of the lungs except that part of the respiratory tract distal to the respiratory bronchioles, it may be assumed that this explanation is the true one The correlation of an active pulmonary vascular bed with the rest of the circulation raises many problems and offers wide opportunities for speculation [1]

Quite a different point, of immediate practical importance, has also been raised by Prof DALY [2] The bronchial arteries supply not only nerves but the bronchial muscles themselves Interference with the circulation might therefore affect these directly or indirectly, and a new ætiological possibility is opened up with regard to asthma Is asthma sometimes due to vascular spasm or disease? The answer to this question is not to be found in the laboratory The most the physiologist can do is to demonstrate the effect on bronchial movement of interfering with the bronchial arteries, and so bring a prima facie case The final investigation must be made at the bedside and in the post-mortem room, and few will dispute the urgency of beginning this at once Prof DALY has pointed to the first path to be followed "To us," he states, "it is becoming increasingly clear that there should be a wider histological examination of the bronchial arteries in all pulmonary cases which come to post mortem examination, for it is only by this means that we shall be able to obtain information as to whether the suggestive physiological experiments I have described are of significance in relation to the control of intrinsic mechanisms of the lungs during life" Those who doubt the significance of these experiments will realise the importance of justifying their scepticism by tangible evidence, and we commend the suggestion of examining bronchial arteries post mortem in pulmonary cases to the attention of morbid anatomists Fortunately uncomplicated asthma rarely leads to death, but a good deal of relevant information must surely be obtainable from fatal cases where asthma has been part of the history

INTESTINAL ADSORBENTS

IN the Far East kaolin or china clay has probably been used for many centuries in the treatment of intestinal complaints PÈRE DEUTRECOLLE, the Jesuit missionary to whom we owe much of our knowledge of the Chinese potter's technique in its later but still golden period, writing in 1712 mentions its employment for the relief of diarrhœa Of late years it has been established in Western therapeutics, mainly on a basis that must be admitted to be highly speculative That fuller's earth kaolin and other silicious earths are—to use the modern term—adsorbents may be looked upon as a very ancient discovery since their properties as cleansing agents and decolorisers and even their capacity for taking glazes when baked, depend upon their adsorptive powers But it is only with the growth of modern colloidal chemistry that the precise conditions under which adsorption operates have been defined Kaolin, for example which consists mainly of SiO_2 has powerful and very general adsorptive powers, particularly in an acid medium (In alkaline media it is almost inactive and the elution of already adsorbed material may even be brought about by alkali) It is argued that such a material taken by mouth should serve to remove bacterial toxins and other undesirable toxic matter from the intestinal canal but if we stop to define the terms of the argument we find ourselves asking What are the bacterial toxins in question ? What part do they play in the production of disease ? Do they in fact exist ? To none of these questions has a satisfactory answer yet been given and as Dr E S **Emery** of Boston says in his excellent review[1] the physician who uses adsorbents is entering a field of therapeutics in which the pitfalls are not clearly indicated and the usefulness of which has not been definitely defined

[2] *Trans med-chir Soc Edinb*, 1936 p 130 (*Edinb med J*)

Powerful adsorbents such as kaolin are double edged weapons and in our efforts to combat the still quite hypothetical condition of alimentary toxæmia we are introducing substances that almost certainly will exercise their adsorbent capacity indiscriminately on enzymes mucus foodstuffs and vitamins and so interfere in an unpredictable way with the delicate mechanisms of nutrition. Further we must remember that we are administering a material which ordinary sense suggests is unsuited to the digestive apparatus it is abrasive and completely non-digestible and it is capable of forming insoluble concretions in the body It is possible moreover that it may be phagocytosed or otherwise lodged in the cells of the alimentary tubes Be this as it may **Emery** points out that kaolin has not escaped criticism in actual therapeutic use Intestinal irritation and inflammation partial intestinal obstruction and even perforation have been ascribed to kaolin treatment and **Hoelzel** has reported the production of intestinal polyposes in rats by treatment with large doses Even these considerations by no means exhaust the difficulties Such precise knowledge as we have of the process of colloidal adsorption is based on the study of comparatively simple systems in vitro and from this knowledge it would be impossible to predict what will happen in the complex and changing environment of the alimentary canal where the hydrogen ion concentration is variable and where there are so many substances useful and useless to the body competing for adsorption There is the further difficulty that adsorbing agents can only be kept in a state of maximum activity under carefully arranged conditions they readily adsorb gases &c and so have their adsorptive activity destroyed or impaired One might ask for example how far their efficacy is affected by any liquid such as oil which may be used as a suspension medium

The question of the action of adsorbents on the intestinal flora is an interesting one, and lends itself to precise study **Braafladt** in 1923 noted that kaolin will adsorb and inactivate large quantities of bacteria Dr W **Smith** on p 438 describes how he has investigated in vitro the action of adsorbents on the flora of the human fæces, and has found that kaolin and in particular kaolin alumina mixtures if given in adequate quantities remove bacteria including *Bacterium coli* almost entirely from suspensions of fæces, as judged by plate-counts of the fæces before and after adsorption This is in itself an interesting observation but it must be related to **Braafladt**'s statement that in the living human being kaolin treatment brings about a change from a proteolytic to an aciduric intestinal flora Allowing that *Bact coli* may be suppressed or replaced by an acidophilic flora in the living subject it by no means follows that any good has been done by the process So far as we know we have lived on relatively good terms with our intestinal flora for countless generations and to any one impressed by the beautiful equilibria of the normal human body it would seem unwise to interfere with them without due forethought That we are being constantly poisoned by our intestinal contents is one of those largely irrational beliefs that must have its roots deep in human nature The address by Prof **Witts** at the front of our present issue is one that we are especially glad to publish because he is attacking one of the major errors of current practice

MINERVA

We have before us[1] in one volume the directory of universities and professional schools in every part of the world compiled by Dr Gerhard Lüdtke with editorial guidance from Dr F Richter For thirty editions this Yearbook of the Learned World contained within the same cover not only this information but similar details of research institutes observatories libraries archives museums and much else Running as it did to 4345 pages it had to be bound in three volumes with consequent loss of some of its time honoured ease of reference The editors of Minerva then decided to carry through the cleavage with the result that the more mobile part of the learned world has its own section which has been kept up to date and reissued at short intervals That is a great convenience for all who have occasion to identify the position of some member of a teaching school in a university or medical school however remote There is rather a disturbing doubt expressed in the preface whether it is physically possible to bring together and to revise such wide spread material ; but it has been done and its success is a testimony to the publisher's love of science in general and of this task in particular We are glad to recognise the public spirit of those who have again produced such a worthy book.

ANNOTATIONS

AN ELECTRON MICROSCOPE

THE term "electron microscope" is used to describe an instrument in which a cathode beam is utilised as the source of energy, much as light is used in the ordinary microscope. There is this important difference that whereas ordinary light can be refracted and an image be formed of an object by a lens or a system of lenses, cathode rays cannot be so refracted. What corresponds to a lens system in the electron microscope is a magnetic field by means of which cathode rays may be focused and an image obtained of a suitable object on a fluorescent screen or photographic plate. The pioneers in the construction of instruments of this kind were Knoll and Ruska in Germany, who utilised methods already in use for cathode rays oscillography. In the January number of the *Journal of Scientific Instruments* a new electron microscope is described. It has been made by Metropolitan Vickers Electrical Co., Ltd., in collaboration with the optical department of the Imperial College of Science. As a beam of electrons may be regarded as light of very short wave-length, and as resolution in the microscope is mainly dependent on the wave length of the light used, it follows that the efficiency of such an instrument is theoretically in proportion to the increased frequency of the radiation used. In the instrument here referred to this would mean that the possible optical limit might be as much as 1000 times greater than with any microscope using visual light. The application of this method to any problem in medical research may be remote. There is much still to be done on the physical side and, as in all advances in microscopy, a new technique will have to be developed in the preparation of material to enable even preliminary experiments to be conducted with any promise of success. How important this factor may be is perhaps indicated by the progress made in using ultra-violet light in microscopy. Objectives for using some wave lengths in the ultra-violet region have been in existence for at least thirty years, but it is only comparatively recently that their use in biological problems has been fully exploited. Even now the complete utilisation of that part of the ultra-violet spectrum which is transmitted through air has not been achieved. The electron microscope is an interesting development in physical method, and its future will be watched by all those interested in any possible developments in microscopy. This at least can be visualised, that the microscope of the future will not be a bench tool, it will be an instrument of precision dependent for its development on the utilisation of radiation, using that term with its full physical meaning.

FLUID LOSS IN INTESTINAL OBSTRUCTION

AMONG the factors that have been blamed for the condition of shock associated with intestinal obstruction is diminution of effective circulating blood volume, due to fluid loss into the tissues and vessels of the obstructed loops. Ian Aird[1] has investigated this factor by experiments on cats, which include simple obstruction of the bowel lumen, obstruction combined with distension of the gut, and venous strangulation. The gain in fluid by the obstructed intestine was measured by comparison of its weight with that of an equal length of normal intestine, Aird concludes from the results that only in venous strangulation of considerable lengths of intestine is the diminution of the volume of circulating blood sufficient to be dangerous to life. A massive strangulation is found clinically in volvulus (particularly in the extensive volvulus of the new born child which is associated with abnormal fixation of the intestine) and in thrombosis of the mesenteric trunks. Simple obstruction by ligature or closed loop occlusion (double ligature) caused losses of fluid that were on the whole insignificant. Comparison of a piece of intestine twelve inches in length, excised immediately above an occlusion, with the twelve inches taken from immediately below showed that the gain in weight of the former did not amount to more than 5½ per cent. of the total blood volume. In a loop of intestine isolated by double ligature the gain in weight was 11 per cent. The effect of distending the isolated loop with air is to cause pronounced congestion, and the accumulation of blood and œdema fluid is much greater than in simple obstruction. In experiments involving one half of the small intestine the gain in weight represented one third of the volume of the circulating blood. Strangulation was studied by inserting a loop of gut into a rubber bag and tying a ligature round the neck of the bag till the mesenteric pulsation was just palpable. The blood entering the loop has no exit by the obstructed veins. Fluid accumulates in the wall of the gut and is poured out into the bag. A lateral anastomosis was formed outside the bag between the entering and returning loops. One third or more of the blood volume can be lost by strangulation of lengths representing a third or more of the small intestine. It has been calculated that the maximum volume of blood that can be thus shunted into the vascular bed and wall of the intestine in gross congestion and distension of the intestine is in the region of 50 to 80 per cent. It is obvious that such a result of massive strangulation is sufficient to account for death without the intervention of other factors such as toxæmia and nervous stimulation which operate in less extensive lesions.

RIGHT-SIDED AORTIC ARCH

ONE result of abnormal development of the aorta is the rare right-sided arch, which curves over the right lung root and passes backwards to the right of the trachea and œsophagus instead of to the left, and then usually crosses to the left behind the œsophagus. During life the condition can only be recognised radiographically, and Dr. Evan Bedford and Dr. John Parkinson are able to give an account[1] of it illustrated by beautifully clear radiograms. Two main types have been differentiated according to whether the left subclavian artery passes in front of or behind the œsophagus after arising from the aortic arch, and they give characteristic pictures. In the anteroposterior view the ascending aorta is abnormally prominent though of varying outline, while there is an absence of the usual knob on the left, the barium swallow shows the œsophagus to be indented on the right instead of on the left. In the first oblique (right anterior oblique) position the picture is usually distinctive, the œsophagus being acutely dislocated forwards by the aortic arch, though this change may not be apparent in the first type. The descending aorta is sometimes visible on the right of the cardiac shadow, and it may be tortuous Other congenital defects—especially Fallot's tetralogy—are often associated with a right-sided arch and the appearances peculiar to them will then be added The symptoms which are not constant, are the result of local pressure and are likely to lead to suspicion of growth intrathoracic goitre or aneurysm Bedford and Parkinson's study is based on 11 cases and attention to the points they raise should lead to correct diagnosis of this interesting congenital anomaly

THE ROUTE OF INFECTION IN POLIOMYELITIS

Most authorities hold that the portal of infection in poliomyelitis is the nasopharynx—at any rate in the great majority of cases—and that the virus reaches the central nervous system by passing along the olfactory nerves after which its spread to the cord is axonal. Briefly stated the evidence in support of this conception is as follows The virus of poliomyelitis is highly neurotropic nerve-cells are essential for its multiplication In poliomyelitis the virus is found in the nasopharynx and in the central nervous system it does not appear in demonstrable quantity either in the blood or in the cerebro-spinal fluid If monkeys are infected by the cerebral route and the course taken by the virus in its spread thence to the anterior horn cells is followed as Fairbrother and Hurst[1] and Faber and Gebhardt[2] have followed it the evidence obtained suggests axonal spread And lastly if the olfactory bulbs are destroyed then, as Schultz[3] has shown the monkey becomes insusceptible to infection by the nasal route Recent work by A B Sabin and P K Olitsky[4] provides an important addition to this evidence They argued that if the virus reached the central nervous system by way of the olfactory nerves one might expect the olfactory bulbs to be the seat of early and constant change and they carried out experiments to see if this was so Working with the M V strain of virus and having ascertained the dosage necessary regularly to infect monkeys via the nose they studied the olfactory bulbs in animals so inoculated. The first rise of temperature in their infected monkeys occurred 4–6 days after inoculation paralysis appearing in another three days In monkeys killed and examined on the fourth day the outer layers of the olfactory bulbs showed diffuse infiltration with polymorphonuclear leucocytes mononuclear cells and lymphocytes, and the mitral cells were frequently necrotic At this time lesions were present in the mesencephalon and pons but were absent from the cord Later when paralysis had supervened the changes in the olfactory bulbs were more conspicuous and well-developed cuffing of the vessels was observed Lesions of varying extent were found in the olfactory bulbs in every one of 18 monkeys infected by the nasal route They were absent in 13 monkeys infected by other routes, such as the cerebral subcutaneous ocular or sciatic It is noteworthy that Sabin and Olitsky only found lesions in the olfactory bulbs in one of three monkeys infected by intravenous injection Lennette and Hudson[5] produced evidence that destruction of the olfactory bulbs protects the monkey against infection with poliomyelitis virus given intravenously They thought that virus introduced into the circulation reached the central nervous system by being excreted on to the nasopharyngeal mucosa and then passing inwards along the olfactory nerves but the experiments of Sabin and Olitsky seem to show that this is not always so The work of Sabin and Olitsky does not merely give additional support to the theory of axonal spread; it goes some way to answer the question of the importance of the nasopharynx as the portal of infection in human poliomyelitis If experimental poliomyelitis in the monkey is comparable to the human disease, then a study of the olfactory bulbs should tell us how often the virus enters the body by the nasopharyngeal route Apparently there are very few observations on the incidence of lesions in the olfactory bulbs in poliomyelitis and this gap in our knowledge will surely be rectified at the first opportunity

BASOPHIL CARCINOMA OF THE PITUITARY GLAND WITH CUSHING'S SYNDROME

Although primary tumours of the anterior lobe of the pituitary gland often invade surrounding structures they very rarely give rise to metastases to remoter parts. Prof. Cohen and Prof. Dible[1] now report a case of Cushing's syndrome in association with a metastasising basophil carcinoma, and this is probably the first of its kind to be recorded The patient was an unmarried woman of 50 and the clinical disturbance referable to the pituitary tumour began seven years before death Examination about eighteen months before death revealed the characteristic clinical features of the syndrome According to the authors all features were present except polycythæmia but analysis of previously recorded cases shows that this is a questionable element of Cushing's syndrome. Of the other characteristic features all but amenorrhœa and obesity seem to have been clearly established. Amenorrhœa in a woman of 48 even though unattended by any conspicuous menopausal symptoms, is of course of doubtful significance the obesity seems to have been transient Biological examination of the urine for sex hormones yielded completely negative results Treatment of the pituitary region with X rays was followed by an improvement which lasted for a little over a year but relapse then rapidly led to death. At necropsy the pituitary gland was greatly expanded by a lobulated basophilic tumour of the anterior lobe Cohen and Dible's statement that the hyaline change described by Crooke in the cytoplasm of the basophil cells was not found in their case is not, as might at first appear, a refutation of Crooke's observation Their description is confined to the tumour cells they do not describe the appearances of the basophil cells in such remnants of the anterior lobe as may have been present in their preparations According to Crooke[2] this change is always found in the basophil cells of the anterior lobe proper and only occasionally in the cells of any tumour In this connexion it is noteworthy that Rasmussen[3] has lately confirmed the presence of this hyaline change in three additional cases of Cushing's syndrome The first was in a woman aged 27 who had a large not definitely basophilic tumour of the anterior lobe The second in a woman aged 44 is remarkable in that no tumour was found either in the pituitary or suprarenal bodies there was no hyperplasia of the suprarenal cortex The third, in a boy of 13, was associated with a suprarenal carcinoma which had metastasised to the lymph nodes and liver Rasmussen also confirms the extreme rarity of these hyaline changes both in normal glands and in glands from patients with hypertension

HISTAMINE AGAIN

ON the assumption that histamine may be responsible for the increased permeability of the vascular bed in congestive cardiac failure, G S Barsoum and Prof F H Smirk[1] using the method of Barsoum and Gaddum[2] estimated the quantity of "histamine yielding substance" or H Y S in the blood of normals and of patients suffering from this type of heart failure They present the following evidence that H Y S is identical with histamine

(1) H Y S , like histamine, is inactivated by histaminase

(2) H Y S fails to cause a contraction of isolated guinea pig's ileum which has previously been desensitised to histamine (but not to other materials which can cause its contraction) by exposure to a high concentration of histamine Similarly, the H Y S will desensitise the guinea pig's ileum to histamine

(3) Equal doses of histamine and H Y S will cause equal contractions of isolated guinea pig's ileum and equal falls of blood pressure in anæsthetised dogs

They found that the H Y S in the whole blood of eight normal humans varied between 0·05 and 0 11 γ per c cm with an average of 0 08 In congestive cardiac failure this amount was increased to 0 08–0 30 with an average of 0 25 γ per c cm — a concentration sufficient to cause flushing of the skin, reduction of blood pressure and histamine headache in normal people By separating the cells and plasma immediately after bleeding the patients, they found that in twelve normals the plasma H Y S averaged about 0·008 γ per c cm , while the red cell H Y S averaged 0 15 In fourteen patients with congestive cardiac failure the plasma H Y S and the H Y S of œdema fluid were normal, but the red cell H Y S averaged 0 46 γ per c cm , varying between 0 08 and 1 00 The H Y S in the cells is inactive until liberated by laking , for unlaked rabbit's cells, which are rich in H Y S , had no action on injection into a cat, whereas an equal quantity of laked cells produced a substantial fall of blood pressure This explains why the raising of the *whole blood* H Y S found in heart failure does not cause symptoms The investigators conclude that it does not account for the increased vascular permeability

In a further communication[3] Barsoum and Smirk demonstrate an increase in the H Y S content of the venous plasma during the phase of reactive hyperæmia following stoppage of the circulation of the arm for 10–30 minutes An increase in the H Y S of the red cells under these conditions is also demonstrated In contrast with these results, Barsoum and Prof J H Gaddum[4] give as normal *blood* histamine, using their method, a range of 0 027–0·05 γ per c cm in five subjects with an average of 0 035—substantially less than the results obtained by Barsoum and Smirk using the same method On the assumption that histamine shock and the shock due to burns are similar, and ignoring the possibility that any increase in the blood histamine may be due to an increase in the concentration of the red cells in the blood, they give results for nine patients with burns which they summarise in the statement that "extensive cutaneous burns cause in man a large rise of blood histamine at about the time when secondary shock is liable to develop " This statement suggests that there may be some relation between the shock and the blood histamine level Their maximum figures for whole blood in five cases described were 0 12, 0 16, 0 20, 0 22 and 0 08, and 0 04 in a sixth patient who did not live long enough to achieve a raised blood histamine Did she die of shock? Their figures are not as high as those obtained for whole blood by Barsoum and Smirk using the same method in cases of congestive cardiac failure, which results were due solely to excess of H Y S in the cells When the great increase of red cells in the blood in burns and the fact that intracellular H Y S has no effect are taken into account, the figures given in this paper become even less significant Further, the authors did not note flushing of the face or other signs of the presence of histamine in the circulation, and it is doubtful whether anyone has done so in cases of burns The distribution of histamine between cells and plasma in such cases must be shown before the conclusion reached can be maintained

HOOKWORM ANÆMIA

ANÆMIA is a symptom and not a disease And in a review of present knowledge of the causes and treatment of hookworm anæmia Colonel Clayton Lane[1] points out the importance of remembering that cure of a symptom does not necessarily remove its cause In order to understand this particular disease he thinks it essential to go back to first principles and he begins his paper with a discussion of the erythron and hæmopoiesis It is therefore perhaps surprising that he accepts without question Sabin's theory of red cell development The normal hæmoglobin level, he agrees, is a controversial matter but believes it essential to recognise that 100 per cent on the Haldane scale should be regarded as a minimum figure for health and that optimum figures should be higher The purpose of treatment in hookworm anæmia should be to raise the hæmoglobin not merely to 80 per cent , which has been accepted as the criterion of cure, but above 100 per cent The extensive studies of Rhoads and others[2] are inconclusive because in the first place they accepted a relatively low level of hæmoglobin as normal, and secondly because they were satisfied with what Colonel Clayton Lane believes to be unreliable methods of testing for the presence of parasites and of removing them when found Their contention, therefore, that it is possible, by treatment with iron alone, to cure hookworm anæmia without disinfestation he regards as non proven He has found no case recorded in which the hæmoglobin level reached 100 per cent Haldane or its equivalent while the patient was still infested Treatment should first remove the worms, and secondly, supply adequate iron He makes a plea for a determined and immediate effort to discover what anthelmintic, new or old, is the best and safest, since under present living conditions unworming is the only way of preventing infection and curing anæmia in hundreds of millions of people Even if the anæmia is to some extent relieved by giving iron without removal of the worms the patient is still a dangerous source of infection to the community

Colonel Clayton Lane's stimulating view is set out in basic English and those who read it will find that the use of a vocabulary of only 850 words—apart from technical terms—lends itself to incisiveness and simplicity

UTERINE CONTRACTIONS

ALL too little is known about the factors governing the contractions of the uterus—a subject of great practical importance Knaus in 1927 published observations on the influence of the corpus luteum and since then a good deal has been found out about the nature of spontaneous uterine activity and the type of response of the muscle to chemical, hormonic, and physical stimuli This varies as is now well known with the species of animal, the phase of sex cycle pregnancy and the stage of pregnancy Knaus and others believed that spontaneous contractions and the reaction of the muscle to posterior pituitary extract are most noticeable about the time of full development of the follicles in the ovary when the secretion of œstrin is high and least during the dominance of the corpus luteum The latter observation has been confirmed by several workers but is disputed by others; for Schultze Moir Tachezy and now E M. Robertson[1] have been unable to demonstrate an altered activity in the response of the uterine muscle to posterior pituitary extract during the luteal phase of the ovarian cycle Robertson s observations were made with the use of a minute rubber balloon inserted into the (non pregnant) uterus filled with fluid and connected to a manometer Twenty records were made in some twelve women, and several examples of tracings are reproduced in his paper The experiments seem to demonstrate clearly the activity of the muscle and the existence of a response to posterior pituitary extract while the uterus is under the influence of an active corpus luteum Such findings throw doubt on the advisability of using preparations of progestin (the corpus luteum hormone) to discourage uterine contractions in a case of threatened abortion But clinicians are persuaded that its use for this purpose is effective and it is possible that during pregnancy progestin may have a desensitising action not apparent at other times

JOHN HUNTER AS A MILITARY SURGEON

IN 1762, towards the end of the Seven Years War our ancient ally Portugal was invaded by Spain and appealed for help with the result that a British expeditionary force under John Campbell fourth Earl of Loudoun, was sent to assist the Portuguese army The Earl had seen service previously in the 45 and in North America; he was an indefatigable worker who also kept his papers and as commander in-chief he then had charge of the medical service as well as of the fighting Three hundred documents from his collection were acquired in 1934 by the Royal College of Surgeons on the recommendation of the honorary librarian Sir D Arcy Power and they have now been investigated by Prof George Gask who described their contents in a special lecture given at the College on Monday last The papers are of much interest not only because of the light they throw on the conditions and equipment of the army medical service of the time but also because John Hunter served in this expedition as a military surgeon

When John Hunter first came to London at the age of twenty he joined his brother William but after ten years with him he contracted a pulmonary affection that it was feared might develop into tuberculosis unless he had a change Accordingly in 1760 he obtained a commission as an army surgeon from the adjutant general, Robert Adair—the original of the well known song 'Robin Adair'—and was sent to Belle Isle off the coast of Brittany which was taken from the French in 1761 When in the following year Portugal was invaded by Spain four regiments of infantry and detachments of the 16th Light Dragoons were sent on from Belle Isle to Portugal where they were joined by two more regiments from Ireland, bringing the total of this B E F to about seven thousand men. The commander in-chief of the allied forces was the Count of Lippe Bückenberg the famous artillerist and he seems to have succeeded in holding the Spanish invasion not by attack but by laying waste the country in front of the enemy and by defending the line of the Tagus so as to cover Lisbon. The hospitals with which Hunter was concerned were thus situated all along this river The military operations were so trifling that some historians ignore them altogether In the returns of the sick there is no mention of a wound and as a rule no diagnosis From one paper however it seems that the chief complaints were fever ague and flux; these as Prof Gask remarked are the age long complaints of the army One of the most interesting of the papers is a list of the officers of the hospital appointed for the use of this force giving the rates of pay per diem The director William Young received 25s a day Two physicians Dr William Cadogan (whose portrait hangs on the stairs of the Royal College of Physicians) and Dr Michael Morris, got £1 each The surgeons John Hunter Francis Tomkins and William Maddox, had to be content with 10s and likewise the two apothecaries Finally came the surgeon s mates at 5s a day each There were 18 of them and although Prof Gask did not say so one suspects that they did most of the work But there was also a female staff attached to the hospital consisting of a matron who received 2s 6d a day two head nurses and five washerwomen at 1s and sixteen nurses at 6d Prof Gask endorsed the value of the washerwomen from his own war experience There is a difference of opinion about the status of the nurses some holding that they were selected from the camp followers, but Prof Gask gave reasons for believing that they had had some hospital training The orders for the discipline of the hospital show that this was under the control of the combatant side and that the duties were not unlike those of the modern military police

As regards John Hunter there are a number of official returns signed by him one of which is a list of the sick on board the hospital ship *Betty* while bound from Belle Isle to Lisbon He seems to have tried to secure the post of deputy-director of the hospital but without success and when Dr Cadogan was invalided home Hunter actually applied for the post of physician but again without getting it Probably the increased income was his chief object He seems to have been in close touch with Lord Loudoun and to have discharged his duties often in difficult circumstances with the vigour and efficiency that all familiar with his character would expect Transport appears to have been a constant trouble for ambulances had not been invented and country carts had to be used unless the journey could be made by boat When Hunter joined the troops at Belle Isle he described his colleagues in a letter home as a dammed disagreeable lot, but the accusation of Jesse Foot that Hunter was quarrelsome on this expedition is not borne out by these Loudoun papers On the other hand they prove that the chief authority that Foot gives for his statement had a vile temper himself, so that his evidence is worthless Prof Gask's lecture will be published in full in the *British Journal of Surgery*

THE EHLERS-DANLOS SYNDROME

In the December issue of the *British Journal of Dermatology and Syphilis* Dr F Parkes Weber writes of one of the rarest of cutaneous congenital abnormalities, only 8 cases of which have so far been recorded in this country Three features are essential for the diagnosis of the Ehlers Danlos syndrome (1) over-elasticity of the skin, which may be limited to certain areas, such as the knees and elbows, or may be more or less general, (2) over extensibility of joints, especially the metacarpo phalangeal of the thumb, and (3) friability or fragility of the skin and its blood vessels, which must not be confused with epidermolysis bullosa as regards the former, or the dangerous hæmorrhagic tendency of the congenital "bleeder" as regards the latter Dr Parkes Weber regards the third feature as the most important, and it should not be ignored in the future recording of cases of "elastic skin" and "double jointed" freaks—an occasional attraction in sideshows and travelling circuses

GAS-PROOF ROOMS

The air-raid precautions department of the Home Office recommend that "in each house a room or rooms should be prepared to prevent the entry of gas, so that it may be safely occupied during a raid in which gas is used" The Cambridge Scientists' Anti War Group has been making experiments to discover whether rooms prepared according to the official instructions are really gas proof They find [1] that such rooms are in fact so leaky that—

> "if the gas outside is strong enough to injure a man fatally in one hour, then he will receive an equal dose in two and a half to four hours in his 'gas proof' room If the gas is much stronger outside and would kill in five minutes, then the survival time in the room would be only half an hour to an hour inside These calculations are made on the assumption that the concentration of the gas remained constant, as it would do if a persistent gas were sprayed down the street"

After pointing out that in working class homes a gas proof room could seldom be provided, they describe experiments showing that gas masks have only a limited value and express doubts about the possibility of protecting young children Finally they comment on the catastrophic results to be expected from attacks on congested areas using gas, incendiary bombs, and high explosives, and illustrate their thesis with accounts of some (not very impressive) tests with the only form of thermite they could obtain To those familiar with what has already been written on the subject their book contains few surprises, but it will no doubt destroy any undue confidence that may be felt in the efficacy of domestic gas proofing The object of the Government is to prepare people's minds against air-attack so that if this comes the public will do its best to avoid asphyxiation and (believing in the measures suggested) will refrain from losing its head The object of the Cambridge Scientists' Anti War Group, on the other hand, is to declare in advance that these measures are of little value and thus frighten the public into considering means of *preventing* war Their book does much to counter optimism about safety against attack, and we agree with them that the facts, however unpleasant, should be faced But the ordinary man is going to say, with some reason, that if it comes to air raids he will certainly accept a Government gas mask, and remain in a gas proofed room—however leaky both may be—rather than be altogether unprotected

INCIDENCE OF TUMOURS OF THE CENTRAL NERVOUS SYSTEM

It is remarkably difficult to form an accurate estimate of the incidence of any one type, or group, of tumours when the study of such a type or group has become the subject of intense surgical specialisation An obvious effect of such specialisation is the attraction of sufferers to centres where the prospects of treatment are best In any general hospital the establishment of a clinic for a particular type of case will naturally result in a great increase of material of such a kind at that hospital, and conversely—a point that is frequently forgotten—in its diminution in neighbouring hospitals In the recent analysis by J H Peers [1] of the tumours of the central nervous system examined at necropsy at the Boston City Hospital during the past 38 years it is perhaps surprising to find that 188 tumours only were found in a total of 5150 necropsies in which the head had been examined, as compared with 1270 tumours, both benign and malignant, in other sites The period covered by this series is from January, 1896, to December, 1934 It would be instructive to know whether the advent of Dr Harvey Cushing to the neighbouring Peter Bent Brigham Hospital had any appreciable effect upon the incidence of intracranial tumours at the Boston City Hospital. The impossibility, at the present time, of correlating the incidence of tumours of the central nervous system with that of tumours of other organs is due to the absence of any general survey comprising sufficiently large figures and free from disturbing factors of the kind indicated It has been stated by Bailey and Cushing in their monograph (1926) that, next to the uterus, the brain is the most common site of tumours, their view however can hardly be regarded as unbiased

Although in the Boston City Hospital series the number of cases in many groups is too small to be significant, it is of interest that in the glioma group the proportions of the different types conform to those of Cushing's much larger surgical series It is not surprising that the metastatic tumours are proportionately more numerous than in Cushing's series, because recognised cases of this kind are less apt to be referred to a neurosurgical clinic

PRINCIPLES OF MEDICAL STATISTICS

VIII—FURTHER PROBLEMS OF SAMPLING χ^2

In the previous section attention was devoted to the appropriate test of the significance between two proportions. Occasions frequently arise however when we need to compare the characteristics of more than two groups For instance instead of comparing the proportion of vaccinated persons who are attacked with small pox with the proportion of unvaccinated persons who are attacked we wish to see whether the proportions attacked vary with the duration of time that has elapsed since vaccination We shall then have a series of differences between groups to interpret For the comparison of such distributions the χ^2 test has been developed (originally by Karl Pearson)

Interpretation of a Series of Proportions

The statistical procedure may best be discussed by means of a concrete example Table VII shows the distribution of intelligence quotients in a group of nearly a thousand children and the number in each intelligence group that were clinically assessed as having normal or subnormal nutrition

TABLE VII—*Intelligence and Nutritional State* *

—	Intelligence quotients—				
	Under 80 %	80–89 %	90–99 %	*100 %* and over	Total
(i) Number of children with satisfactory nutrition	245	228	177	219	869
(ii) *Number of children with unsatisfactory nutrition*	31	27	13	10	81
(iii) Total number of children observed	276	255	190	229	950
(iv) Percentage in each intelligence group that had unsatisfactory nutrition	11·2	10·6	6·8	4·4	8·5

* From the Relation between Health and Intelligence in School Children by N J England (1936) *J Hyg Camb* 36 74

The percentages in the last line of the table show that amongst the more intelligent children there were proportionately fewer instances of subnormal nutrition and the regular progression of the percentages from 11·2 to 4·4 as the intelligence quotient rises suggests that this relationship is unlikely to have arisen merely by chance It is clear however that if another sample of 950 children were taken at random from the same universe of children we should not necessarily find in the different intelligence groups exactly 11·2, 10·6 6·8 and 4·4 per cent with unsatisfactory nutrition. Each of these percentages is certain to vary from one sample to another and the smaller the sample the more, as has been previously shown they are likely to vary The question at issue then becomes this is it likely that the magnitude of the differences between these percentages and also their orderly progression could arise merely by chance in taking samples of the size given in line three? Is it likely in other words that if we had observed the whole universe of children from which the sample was taken the percentage with unsatisfactory nutrition would be just the same in each intelligence group? To answer that question the assumption is made that the percentage with *unsatisfactory nutrition ought to be identical* in each of these groups—i e that intelligence and nutrition are unrelated We then seek to determine whether that assumption is a reasonable one by measuring whether the differences *actually* observed *from* the uniform figure might frequently or only infrequently arise by chance in taking samples of the recorded size If we find that the departure from uniformity is of the order that might frequently arise by chance then we must conclude that the varying percentage of children with unsatisfactory nutrition in the different intelligence groups *suggests* that intelligence and nutrition are associated but that these differences are not more than might have arisen by chance and might vanish if we took another sample of children We must therefore be cautious in drawing deductions from them If on the other hand we find that the differences from our assumed uniformity are such as would only arise by chance very infrequently then we may reject our original hypothesis that each of the groups ought to show the same percentage For if that hypothesis were true an unlikely event has occurred, and it is reasonable to reject the unlikely event and say that we think the differences observed are real in the sense that they would not be likely to disappear (though they might be modified or increased) if we took another sample of children of equal size

THE TECHNIQUE INVOLVED

The statistical technique therefore involves—

(1) Calculating *how many children in each intelligence* group would fall in the satisfactory nutrition category and how many in the unsatisfactory nutrition category on the assumption that intelligence and nutrition are unrelated so that the proportions in the nutrition categories ought to be the same in each group

(2) Calculating the differences between these numbers expected on the hypothesis of no relationship and the numbers actually observed.

(3) Calculating whether these differences are of a magnitude likely or unlikely to be due to chance

The first step is to determine what is the uniform percentage with unsatisfactory *nutrition that* we should expect to observe in each intelligence group if intelligence and nutrition are unassociated. Clearly that figure must be the percentage of malnourished children in the *universe from* which our sample was taken; that is the figure we should, apart from sampling errors expect to obtain in each intelligence group if this characteristic is not associated with nutrition. *We do not know that* figure but as an estimate of it we may take the proportion of malnourished children in our sample as a whole—namely 8·5 per cent Our assumption then is that the *proportion of malnourished* children ought to be 8·5 per cent. in each intelligence group If that assumption is true should we be likely to observe in a sample of the size given, percentages of 11·2 10·6 6·8 and 4·4 *merely* by chance? We must first calculate the number of children expected in each intelligence group on this hypothesis that 8·5 per cent. of them ought to have belonged to the malnourished *category* and *91·5 per cent* to *the* satisfactorily nourished category These figures are given in italics in Table VIII being calculated by simple proportion—e g there were 276 children whose *intelligence quotient* was *below 80 per cent*; we expect 8·5 per cent of these 276 or 23 to be malnourished and 91·5 per cent or the remaining 253 to be satisfactorily nourished

TABLE VIII—*Calculation of* χ^2

—	Intelligence quotients—				
	Under 80 %	80–89 %	90–99 %	100 % and over	Total
(i) Observed number with satisfactory nutrition	245	228	177	219	869
(ii) Expected number on hypothesis that nutrition and intelligence are unrelated	*253*	*233*	*174*	*209*	*869*
(iii) Difference, observed minus expected	−8	−5	+3	+10	
(iv) (Difference)^2	64	25	9	100	
(v) (Difference)^2 ÷ Expected number	0·25	0·11	0·05	0·48	
(i) Observed number with unsatisfactory nutrition	31	27	13	10	81
(ii) Expected number on hypothesis that nutrition and intelligence are unrelated	*23*	*22*	*16*	*20*	*81*
(iii) Difference observed minus expected	+8	+5	−3	−10	
(iv) (Difference)^2	64	25	9	100	
(v) (Difference)^2 ÷ Expected number	2·78	1·14	0·56	5·00	
Total—					
Observed	276	255	190	229	950
Expected	*276*	*255*	*190*	*229*	*950*

The next step is to calculate the differences between the observed and expected entries. These, given in the third line of each half of the table, show that there are in fact more children of low intelligence with subnormal nutrition than would be expected on our hypothesis of equality and fewer with subnormal nutrition in the higher intelligence groups than would be expected on that hypothesis—e.g., of children in the under 80 per cent. intelligence group 31 had unsatisfactory nutrition whereas we expected only 23; of children in the over 100 per cent. intelligence group there were only 10 with unsatisfactory nutrition whereas we expected 20. These differences if added together according to their sign must come to zero. To get rid of this difficulty of sign, and for mathematical reasons underlying the test, each difference is squared (as shown in line iv). Finally the following point must be observed. If the number expected in a group is, say, 75, and the number actually observed is 100, the difference of 25 is clearly a relatively large and important one, since it amounts to one third of the expected number. On the other hand, if the number expected in the group is 750 and the number actually observed is 775, the difference of 25 is a relatively small and unimportant one, since it amounts to only 3·3 per cent. of the expected number. To assess the importance of the difference, its square is therefore divided by the number expected in that category (in the first case above this gives a value of $(25)^2/75$ or 8·3, in the second case $(25)^2/750$ or only 0·83). The sum of these values is known as χ^2. In this table it equals $0·25 + 0·11 + 0·05 + 0·48 + 2·78 + 1·14 + 0·56 + 5·00 = 10·37$.

In other words χ^2 is equal to the sum of all the values of

$$\frac{(\text{Observed number} - \text{Expected number})^2}{\text{Expected number}}$$

THE INTERPRETATION OF THE χ^2 VALUE

χ^2, it will be observed, will be zero if the observations and expectations are identical; in all other cases it must be a positive value, and the larger the relative differences between the observed and expected values the larger must the value of χ^2 be. Also the more sub groups there are in the table the larger χ^2 may become, since each sub group contributes a quota to the sum. Therefore in interpreting the value of χ^2 account must be taken both of the value itself and of the number of sub groups contributing to it. In fact, although its mathematical foundation is complex, the interpretation of χ^2 is simple by means of published tables—e.g., Table III in Fisher's "Statistical Methods for Research Workers" (Sixth edition. Edinburgh and London: Oliver and Boyd. 1936. 15s.), of which an illustrative extract is given at the end of this article. These tables show whether the various differences found between the observed and expected values, as summed up in χ^2, are sufficiently large to be opposed to our hypothesis that there ought to be a uniform proportion of malnourished children in each intelligence group. For instance in the present example $\chi^2 = 10·37$ and the number of independent sub groups is 3 (this number will be referred to in a moment); for these values Fisher's table gives a probability of somewhat less than 0·02—see table below. (The exact probability can be obtained from larger tables but is not always important, the main question being whether this value of χ^2 is one which is likely or unlikely to have arisen by chance.) The meaning of this probability is as follows. If our hypothesis that we ought to have observed the *same* percentage of malnourished children in each of the intelligence groups is true—i.e., we are sampling a universe in which malnutrition and intelligence are not associated—then in the different intelligence groups of the size shown we might have reached merely by chance the differing malnourished proportions actually observed (or even larger differences from the uniformity expected) about once in fifty times (0·02 equals 2 in 100). In other words if we had 50 separate samples of 950 children with this distribution of intelligence and ought to observe within each the same percentage of malnourished children in the intelligence groups, then in approximately only one of these 50 samples should we expect the actual proportions of malnourished children in the intelligence groups to differ between one another, by chance, by as much as (or more than) the proportions we have observed here. Once in fifty we may take to be an unlikely event and may therefore conclude that our original testing hypothesis of equality is wrong, and that it is more likely that the intelligence groups really differ in the incidence of malnourishment. If on the other hand our χ^2 value had turned out to be 4·64, then the probability figure would have been 0·2. In other words, once in five trials we might reach differences of the observed magnitude between observation and expectation merely by chance. Once in five trials is a relatively frequent event, and we should have to conclude that the differences between the proportions of malnourished children in the intelligence groups might easily have arisen by chance, and we can draw from them no more than very tentative conclusions.

As with all tests of "significance" it must be observed that the final conclusion turns upon probabilities. There is no point at which we can say the differences could not have arisen by chance or that they must have arisen by chance. In the former case we say chance is an unlikely cause, in the latter that it could easily be the cause. It may not have been the cause in the latter—real differences may exist—but our data are insufficient for us to rule out chance as a valid hypothesis

HOW TO USE FISHER S χ^2 TABLE

Finally we must consider the number of sub groups or cells, in the table contributing to χ^2

In Table VII (or VIII which shows the calculations on the data of Table VII) there are 8 such values contributing to the sum In finding P the probability from Fisher s table we took the number n, to be only 3 The rule to be followed in tables of the type taken above as an example is that n is the number of cells which can be filled up independently of the totals in the margins at the side and bottom of the table In Table VII the expected numbers of malnourished children in three of the intelligence groups must be found by simple proportion by applying 8 5 per cent to the total number of children in each of those three groups Having found those three values all the other expected values can, however be found by simple subtraction since the total expected values vertically and horizontally must be the same as the observed values—e.g having found the expected values of 23 22 and 16=61 in three intelligence groups, the expected number in the fourth group must be 20 since the total must be 81 (8 5 per cent of 229 is nearly 20) Similarly if 23 malnourished children are expected in the intelligence group of " under 80 per cent then the well nourished in that intelligence group must be 253 for the total children of that type is 276 Hence only 3 values in this table need to be found independently by applying proportions and the remainder can be found by subtraction.

In any practical problem the number of expected values which need to be found independently by simple proportion can easily be ascertained on inspection of the table alternatively they can be found by means of the rule $n=(c-1)\ (r-1)$ where c is the number of columns excluding the total columns and r the number of rows in the table—e g in Table VII $n=(4-1)\ (2-1)=3$ It is with this n that Fisher s table must be consulted

It may be pointed out that in the above example the expected numbers were taken to the nearest whole number for the sake of simplification, but it would have been more accurate to retain one decimal and in practice this should be done A warning may be added that if the expected number in any cell is less than 5 the χ^2 value is liable to be exaggerated and the probability derived from it may be inaccurate In such cases adjacent columns should if possible be amalgamated to give larger expected numbers.

The following table is a short extract given for illustrative purposes from Fisher s table In the latter the χ^2 values are tabulated for each value of n from 1 to 30 and for 13 probability values.

Table of χ^2

n	$P=0{\cdot}90$	0·70	0·50	0·20	0·05	0·02	0·01
1	0·0158	0·148	0·455	1·642	3·841	5·412	6·635
3	0·584	1·424	·366	4·642	7·815	9·837	11·341

n is the number of cells that needed to be filled independently (as defined above) in the table of observations under study In the centre of Fisher s table are set out the values of χ^2 At the top is the probability arising from the observed value of χ^2 for a given value of n For instance in the example taken above n was 3 and χ^2 was 10 37 Glancing along the χ^2 values against $n=3$ we see that a χ^2 of 9 837 gives a P or probability of 0·02 and one of 11 341 gives a P of 0·01 Our value of 10 37 must therefore give a P of somewhat less than 0·02 If on the other hand χ^2 had been 4 642 we see that the P against that value is only 0 2 If n had been 10 and the value of χ^2 found were 18 307 then P would be 0·05 As a conventional level a P of 0·05 is usually taken as significant —i.e the proportions observed in the different groups under examination would only show by chance a departure from the assumed uniformity as great as (or greater than) that actually observed once in twenty times But, as pointed out in the last section, the worker is entitled to take any level of significance he wishes so long as he makes his standard clear

Summary

In practical statistics occasions constantly arise on which we wish to test whether persons who are characterised in some particular way are also differentiated in some second way—e.g whether persons of different hair colour have also a different incidence of say tuberculosis Suppose we take a random sample of the population divide them into groups according to their hair colour and then compute for each of these groups the percentage of persons with active tuberculosis These percentages will probably not be identical even if hair colour and incidence of tuberculosis are *not* associated Owing to chance they will vary between themselves We need a measure to show whether such observed differences in incidence are in fact likely or unlikely to be the result of chance. To this type of problem the χ^2 test is applicable. A. B H

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 6TH 1937

Notifications—The following cases of infectious disease were notified during the week: Small pox 0; scarlet fever 1066 diphtheria 1253; enteric fever 61 pneumonia (primary or influenzal) 3140 puerperal fever 50; puerperal pyrexia 148; cerebro spinal fever 87; acute poliomyelitis 3; encephalitis lethargica 6 dysentery 30; ophthalmia neonatorum 78 No case of cholera plague or typhus fever was notified during the week.

Notifications of acute pneumonia in England and Wales were 93 per cent. above expectation in London itself 17 per cent below

The number of cases in the Infectious Hospitals of the London County Council on Feb 12th was 3437 which included, Scarlet fever 809 diphtheria 1006 measles 22; whooping cough 607 puerperal fever, 0 mothers (plus 1 babies) encephalitis lethargica 281 poliomyelitis 3 At St. Margaret s Hospital there were 17 babies (plus 7 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns, including London there was no death from small pox 4 (1) from enteric fever 3 (0) from measles 5 (1) from scarlet fever 40 (1) from whooping-cough, 62 (6) from diphtheria 37 (13) from diarrhoea and enteritis under two years and 976 (101) from influenza The figures in parentheses are those for London itself

Of the 783 deaths from influenza in the great towns of England and Wales outside Greater London the largest total were reported from Manchester 51 Birmingham 50, Sheffield 37 Liverpool 35 Leeds 30 Plymouth 15 Derby 12, Bristol 11 Ipswich 10 Of these only Birmingham Sheffield and Leeds showed a drop from the previous week. The corresponding figures for Scottish and Irish towns were Edinburgh 37 Glasgow 39, Dublin 43 Belfast 18

Darlington reported 1 death from enteric fever Liverpool the other 2 Bolton had 4 deaths from whooping-cough, Middlesbrough 3 Willesden, Wood Green and Manchester each Fatal cases of diphtheria were reported from 24 great towns Birmingham 7 Liverpool 5 Hull and Manchester each 4 Swansea 3

The number of stillbirths notified during the week was 202 (corresponding to a rate of 42 per thousand total births) including 50 in London

THE NEUTRALISING VALUE OF POLIOMYELITIS CONVALESCENT SERUM

FROM THE 1934 EPIDEMIC IN DENMARK

By G. Hardy Eagles, M.D. Toronto, D.P.H.
MEMBER OF THE SCIENTIFIC STAFF, LISTER INSTITUTE OF PREVENTIVE MEDICINE, LONDON

Claus Jensen, M.D.
DIRECTOR OF DEPARTMENT OF BIOLOGICAL STANDARDS, STATE SERUM INSTITUTE, COPENHAGEN; AND

E. Juel Henningsen, M.D.
EPIDEMIOLOGIST, STATE DEPARTMENT OF PUBLIC HEALTH, COPENHAGEN

During 1934 there was an extensive epidemic of poliomyelitis in Denmark. Aside from its magnitude this epidemic was of especial interest because during the latter half of the year nearly 4500 carefully diagnosed cases were taken into hospital, of which 4000 were in the early systemic phase of the disease. Unlike most epidemics elsewhere it occurred in a population where, owing to the long standing and systematised methods of public health administration, the medical profession and the general population are amenable to centralised control and uniform policy. The value of this appeared in the ease with which convalescent serum was collected. A preliminary report on the epidemiology and clinical features of the outbreak, and the use of convalescent serum, has appeared elsewhere and may be consulted for details (Jensen 1935).

The 1934 epidemic followed a smaller one in the previous year, when some evidence of the value of convalescent serum was obtained although the supply was inadequate. It was anticipated that in the summer and autumn of 1935 there would be a third epidemic for which it was desirable to have on hand an adequate supply of suitable convalescent serum.

In almost all previous epidemics elsewhere serum has been taken from old paralytic cases of poliomyelitis with crippling evidence of the disease. These were doubtless selected because of the ease with which they could be traced and because the diagnosis was certain. It may, however, be questioned whether such donors are likely to yield sera with the highest possible content of protective antibody. It is well known that the capacity for antibody production against specific antigenic stimuli varies immensely, and in poliomyelitis the paralytic cases may represent individuals with a low response. In virus infections the time interval between infection and the peak of antibody content in the serum appears to follow the same course as in most other infections. Brodie (1932a and b) has shown that in animals the response to an intradermal dose of poliomyelitis virus reaches a maximum within 20–30 days, and that after a second dose antibody forms rapidly with a maximum in 10–18 days. If the same is true of man it follows that serum must be collected much earlier than is usual if the greatest concentration of antiviral principles is to be obtained. In Denmark the selection of donors was made with this in mind.

The principal objectives in reinvestigating the protective power of convalescent serum were first, to use the opportunity here presented of testing pools of serum from selected donors in quantities sufficiently large to be of practical use in epidemics; and, secondly, to discover whether, by selection of donors at certain phases during convalescence, serum of higher potency might be obtained.

All the serum was taken from fresh cases representing three different clinical groups of patients—namely, (*a*) frankly paralytic cases, (*b*) non paralytic cases, and (*c*) abortive cases. The "abortive" cases were those in which very slight and transitory symptoms appeared in persons who were in close relationship to unquestionable paralytic and non paralytic cases in families or institutions. It has seemed reasonable to assume that in such cases the infection is abortive by reason of their greater capacity to resist an infective dose of virus and also to produce antiviral substance quickly. The interval between the onset of disease and bleeding was therefore shortest in these donors.

Serum was collected, stored in ampoules without preservative, and tested for sterility in Denmark. To avoid delay and possible deterioration sera were transported to England by air mail and kept in the cold room during the test period. The selection of cases, the preparation of sera, and the entire epidemiological part of this investigation were carried out by C. J. and E. J. H., while the virus neutralisation tests in monkeys were performed by G. H. E. in England.

PREPARATION OF "STANDARD" VIRUS FOR USE IN THE TESTS

The cervical and lumbar enlargements from twelve cords of monkeys which had recently been killed at the height of complete paralysis were stripped free of the meningeal covering and minced. This rather coarse mince was stored in 50 per cent. saline glycerin at about −10° C. The preparation of minced material from several cords avoided the possibility of using sections of the same or different cords possessing varying concentrations of the virus. It also provided a sufficient amount of virus of about the same virulence to extend throughout the entire investigation. Since it is well known that virus infected cords retain their virulence for many months when kept in glycerin at a temperature below freezing point, this method served to provide a virus of uniform infectivity. The importance of using a uniformly infective dose of virus for comparative tests was clearly shown in the observation of Schultz and Gebhardt (1935b) that the incidence of serum treated animals which escaped infection bore some relationship to the dose of virus with which the animals were inoculated. When 6.6 M.I.D. of virus were used a certain number of animals were protected by serum. With larger doses of virus the same serum prolonged the incubation period but none of the animals escaped infection.

When samples were required for neutralisation tests the mince was thoroughly stirred and approximately the required amount removed and washed in three changes of normal saline. The exact amount for the test was then weighed, ground with sand, diluted, and mixed thoroughly with sufficient normal saline to make a 10 per cent. suspension. The suspension was spun at 3000 to 4000 r.p.m. for fifteen minutes and the uppermost portion of the supernatant removed. When neutralisation or infectivity tests were to be made a fresh 10 per cent. suspension was made from the "standard" minced virus.

Titration of "Standard" Virus.—Decimal dilutions of the 10 per cent. virus supernatant were made in normal saline from 10^{-1} to 10^{-6}. These were incubated at 37° C. for 2 hours and allowed to stand in the cold room overnight. 0.5 c.cm. of each dilution was inoculated intracerebrally into young rhesus monkeys under ether anæsthesia. Monkeys receiving dilutions 10^{-1}, 10^{-2}, 10^{-3} were all completely paralysed on the sixth day following

TABLE I—*Convalescent Serum Pools and Protective Titre*

—	Serum pool	No of cases in pool	Special features	Virus.	Dilution of serum giving complete protection	Dilution of serum followed by complete paralysis	Value in protective "units" per c cm serum
GROUP I—FIRST BLEEDING				M.L.D			
(1) *Paralytic cases* Average 39 days after onset of meningitic state	A 253	67		1000	No protection undiluted		< 1,000
	A 239	22			1 in 20	1 in 40	40 000
(2) *Non paralytic cases.* Average 20 days after onset of meningitic state	B 200	184			1 in 5	1 in 10	10 000
	BB 444	33	Blood group B	"	1 in 75	1 in 100	150 000
	B 505	535	1st test.	"	1 in 40	1 in 60	80 000
			2nd		1 in 20	1 in 40	40 000
(3) *Abortive cases* Average 13 days after onset of meningitic state	O 108	8			1 in 50	1 in 75	100 000
	O 354	20			1 in 5	1 in 10	10 000
	O 261	1	Single serum from O 354		1 in 5	1 in 10	10 000
GROUP II—SECOND BLEEDING							
(1) *Paralytic cases* Approximately 4 months after onset of meningitic state.	A 604	48	*Unconcentrated*		1 in 10	1 in 20	20 000
	A 604 concentrated		Pseudoglobulin concentrated approx. 8 times		1 in 50	1 in 75	100 000
			Euglobulin concentrated approx. 5 times		No protection undiluted		< 1 000
(2) *Non paralytic cases* Approximately 4 months after onset of meningitic state	BB 500	48	Blood group B		1 in 20	1 in 40	40 000
	B 501 B 502 B 506	31	Blood group A		1 in 20	1 in 40	40 000
			Seitz filtered B 501		1 in 20	1 in 40	40 000
			B 501 dried and reconstituted		1 in 75		> 150 000
GROUP III—CONTROL SERA.							
(1) Normal adult sera pooled	Lister	23			1 in 50	1 in 75	100 000
(2) Claus Jensen		1	Single serum from normal pool		1 in 10	1 in 25	20 000
(3) Prague II			Old convalescent.		1 in 25	1 in 50	50 000
(4) 13					1 in 25	1 in 50	50 000
(5) Hyperimmune horse serum			Lister Institute		1 in 75	1 in 100	150 000

< = less than > = more than.

inoculation and were killed The remainder of the series showed no sign of paralysis. Sections from the nervous tissue of paralysed animals showed typical lesions

Test Dose of Virus—0·5 c cm. of a 10^{-3} dilution of the virus was assumed for practical purposes to contain one minimal paralysing dose (M.P D) In order to allow for individual variation in susceptibility of monkeys to the virus 0·5 c cm of a 1 per cent virus supernatant (1000 M.P.D) was selected as the test dose for all neutralisation tests Throughout the investigation this dose always caused complete paralysis within ten days in the control animals

Serum neutralisation Tests

In the first instance all sera were tested undiluted diluted 1 in 10 and 1 in 20 in normal saline. Equal parts of 1 per cent virus and the serum were mixed incubated for 2 hours at 37 C and stood in the cold room over night. A control of equal parts of virus and normal saline was included. Next morning 1 c cm of each virus-serum mixture was inoculated intracerebrally in young healthy *rhesus* monkeys A control monkey received at the same time 1 c cm of the virus-saline mixture When all test animals remained unaffected for three weeks after inoculation fresh monkeys were inoculated with higher dilutions of each serum until an end point of protection was reached and paralysis resulted In all but one instance an initial paralysis progressed rapidly to the complete stage

Results—The dilutions of serum which afforded protection against 1000 M.P.D of the virus are set out in Table I It has been assumed for practical purposes in expressing values that twice the amount of serum actually used in the neutralisation tests would give twice as much protection There is however no experimental proof that this is in fact, true The main object in adopting this scheme of expression has been to denote the values of the different sera in terms of a unit volume (1 c cm) since this might prove useful in future in the event of a standard convalescent human serum from poliomyelitis cases being set up and issued.

Discussion

From this investigation it is difficult to draw clear cut conclusions in favour of the thesis upon which the work was largely based—namely that sera taken early in convalescence from poliomyelitis have a *significantly higher protective titre* than those taken later A source of error which might well make an appreciable difference in the protective value of the sera appears when the number of individual sera in each pool are compared This would *not be serious* if it could be assumed on experimental evidence that each serum in any given pool possessed approximately equal protective value But to make this assumption would not be justifiable in view of the results of other investigators Shaughnessy Harmon and Gordon (1930a and b) found considerable variation in titre of individual convalescent sera, 3 of the 14 sera tests having failed to neutralise in any dilution Schultz and Gebhardt (1931) and Jungeblut and Smith (1932) also obtained some negative results In our own control group evidence of wide variation was suggested when one serum (Group III (2)) from a *pool* of normal individuals gave protection in a dilution of 1 in 10 whereas the pool itself protected in a dilution of 1 in 50 Under such circumstances the dilution factor must influence the titre of a pooled serum in direct ratio of the *number of high titres to* low in the mixture

The single serum just mentioned is of interest in one more respect It was obtained from a man (C J) who for more than two months every day had been in close contact with numerous fresh cases of poliomyelitis in all phases of the disease Yet it was relatively poor in viricidal antibodies (20,000 protective " units " per c cm)

It is well known that individual variation in susceptibility to the virus may be found in the same race of monkeys Even when large enough doses of virus are used to ensure that all control animals become completely paralysed variations in protection appear in different monkeys with the same dilution of a serum Two instances were found in our series in the case of B 505 when a dilution of 1 in 40 gave complete protection to one monkey but not to a second one against the same dose of virus, the test being made on the same day, and again in the neutralisation tests with hyperimmune horse serum Here on one occasion protection was obtained in dilutions 1 in 25 and 1 in 75 of the serum, but with 1 in 50 complete paralysis occurred on the eighth day When the serum was retitrated complete protection was obtained with a 1 in 50 dilution In both cases, however, a dilution of 1 in 100 failed to neutralise and it appeared reasonable to accept the end point of protection as 1 in 75

Since, with these exceptions, only one animal was used for each dilution throughout the series it is not possible to say how far such variation may have influenced our results To this may possibly be attributed the fact that pool B 502 gave so much less protection than the same pool (B 506) when it had been dried and reconstituted. It is probably very unusual, however, for animals to vary so widely as this would suggest and some other explanation must be sought

BLOOD GROUPS

The high protective value in Group I of pool BB 444, consisting of donors belonging to blood group B, recalls the work of Jungeblut and Smith (1932), who found that cases of poliomyelitis were fewer in members of this group, the sera of a greater proportion of normal persons neutralised in this than in other groups, and the pooled sera of this group neutralised in higher dilution than that of other groups When convalescent sera were tested for neutralising power a higher percentage was obtained in those from Group B In this connexion the observations of Madsen, Engle, C Jensen, and Freuchen (1936) are of interest With the clinical material in the epidemic in Denmark with which, for the greater part the present investigation deals, they were unable to relate the blood group of the patients to susceptibility or resistance to the attack In our series comparison of blood groups A and B can be made only in Group II (B 501 and BB 500) where no difference in neutralising power was found

TABLE II

Protective Power of Sera in Relation to Blood Group

Serum pool	—	Blood group	Virus	Dil of serum giving complete protection	Dil of serum followed by complete paralysis	Value in protective units " per c cm of serum
BB 444	First bleeding	B	M P D 1000	1 in 75	1 in 100	150 000
BB 500	Second bleeding	B		1 in 20	1 in 40	40,000
B 501	Second bleeding	A	,,	1 in 20	1 in 40	40 000

The full data as to number of individuals in the pools and time of bleeding appear in Table I

It may be mentioned here that the only striking example of a higher titre in serum taken early in convalescence over that taken later is found in blood group B (BB 444 and BB 500)

In order to make this point clearer the data regarding protection by blood group have been recast in Table II

THE BEST SOURCE OF CONVALESCENT SERUM

From our investigation, selected convalescent sera appear to have little advantage over serum from normal adults when the titre of the control pool is compared with the values obtained in the convalescent groups I and II A strict parallel between normal serum and convalescent pools cannot, however, be made since only one sample of pooled normal serum was tested as compared with eleven from convalescents The relatively high neutralising value of two pooled sera from convalescents of long standing compared favourably with many of the convalescent pools This has been the experience of most other investigators who have worked along similar lines

In a preliminary report it has been stated (Eagles, cited by C Jensen, 1935) that the pooled sera from abortive and non paralytic cases appeared to have higher neutralising value than from paralytic cases At that time the investigation was incomplete, the results now available call for qualification of the earlier statement in that when a larger number of pools was examined both high and low neutralising titres occurred in the pools from all three types Investigation on a larger scale might make this point clearer, especially in view of the fact that, on the whole, the neutralising values are higher than in the paralytic cases

NEED FOR STANDARDS

In our experiments an attempt has been made to use a standardised technique in order to make the results comparable We consider this important because the results of neutralisation tests in published data are often stated only vaguely, thus "nine out of the nineteen sera neutralised the virus when the serum had been diluted 1 in 60," or "such sera regularly neutralised the virus emulsion when diluted 1 in 20, but did not neutralise in dilution 1 in 30" As the method of preparing the virus emulsion and the test dose used is not always given, it is obvious that such results are not comparable If the possible effect of convalescent serum therapy is to be correctly evaluated, if the maximum of information is to be obtained from clinical trials, and if the results in different countries are to be rendered comparable, it is essential that all anti poliomyelitis sera used experimentally and clinically should be tested *in relation to a common standard and their potency expressed in terms of this standard* This has been emphasised by Th Madsen and C Jensen (1935), who have proposed an international standard for anti poliomyelitis convalescent serum

Even with the technique employed by us the results, for this reason, cannot be regarded as quite comparable If future work of this kind were to be undertaken it would therefore seem advisable to use, if possible, both the test virus and the proposed international standard serum preserved in the dried state Furthermore, the testing of an unknown serum should always include a control series with the test dose of virus against varying amounts of the standard serum These tests should be carried out simultaneously and under strictly comparable conditions, and, despite the expenditure incurred, a sufficiently large number of animals for each dilution of the unknown serum and the standard serum to guard against variation in the susceptibility of an individual monkey to the serum virus mixture.

IMMUNE HORSE SERUM

In the control group of sera a sample of hyperimmune horse serum prepared in the serum department of the Lister Institute has been included for comparison with our selected convalescent pools. It will be seen that pool BB 444 has equal neutralising value with the horse serum and C 108 has a value only slightly less There is hesitation in using immune horse serum in the treatment of poliomyelitis These results show that it is possible to secure large quantities of convalescent serum with a neutralising value which compares favourably with hyperimmune horse serum.

VALUE OF SERUM IN TREATMENT AND PROPHYLAXIS

The question naturally arises whether the possible value of serum therapy in combating poliomyelitis justifies further investigation In the Danish as well as in other recorded epidemics the value of serum therapy has been questionable owing to the absence of an adequate control group The large proportion of untreated cases that make an uneventful recovery confuses the issue still further It is impossible to judge the value of serum in contacts since many with or without serum never contract the disease. It is as a prophylactic and in the pre paralytic stage that serum may be of value if massive repeated doses of a tested highly neutralising serum are employed Schultz and Gebhardt (1935a and b) have shown that in the experimental disease immune serum was of limited value as a prophylactic The infecting dose of virus was important Large amounts of high titre immune serum might protect monkeys against small doses of virus The effect of the serum was, apparently to diminish the quantity of virus free to initiate infection and the larger the initial dose of virus the less effective became the serum It is probable that some such ratio between virus and antibody determines the outcome in serum treated cases while in the experimental disease under such conditions even small differences in susceptibility of the animals would become important The great affinity of the virus for nervous tissue the ease with which it passes along the olfactory nerve to the central nervous system and its possible absence at all times from the blood stream may assure it a high degree of protection from serum antibodies once the disease is established The present trend of preventive measures—at any rate in America—is towards the application of chemical substances to the nasal mucous membrane, to protect the endings of the olfactory nerve from invasion (Armstrong and Harrison 1935 Sabin Olitsky and Cox 1936 Schultz and Gebhardt 1936) But should such measures prove effective for routine prophylactic treatment, there will still remain a demand for serum since no other form of specific treatment is at hand in combating the established disease.

That convalescent or other sera are of real value in human poliomyelitis is not proven Almost uniformly however the clinical evidence points to an improvement in symptoms and general condition when convalescent serum is employed and to disregard this fact would be unwarranted Moreover the behaviour of serum in the experimental disease cannot be used as a true index of its effects on the natural course of human poliomyelitis Harmon and Harkins (1936) express the opinion based upon an analysis by Harmon (1934) of 4400 patients treated with serum that convalescent and other specific serum therapy should be continued. The serum used should be of the highest possible neutralising value as judged by animal tests In a survey of the literature dealing with neutralising antibody in the blood of human convalescents Harmon (1936) draws attention to the high percentage (about 40) of cases in which neutralising antibody is absent In normal persons the antibody content rises with advancing age and the same survey shows that at fifteen years of age 73 per cent. have neutralising antibody Since it is impracticable to test each serum separately and to pool only those of high value full neutralisation tests should be carried out on serum pools that are intended for use in practice if those of low titre are to be avoided. Pools of relatively low neutralising titre need not be discarded. Our results show that these may be fractionated, and by concentration of the pseudoglobulin fraction a serum of relatively high value be obtained (A 604 A 604 conc.)

SUMMARY

The protective value, as judged by neutralisation tests in monkeys of human convalescent serum collected from the Danish epidemic of 1934 has been investigated. Separate pools were obtained from abortive non paralytic, and paralytic cases 13–20 days after the onset of the meningitic state and compared with similar pools collected about four months later Some evidence has been obtained that pooled serum taken very early from non paralytic and abortive cases may have higher neutralising value than from paralytic cases but this is not sufficiently definite to be convincing Serum taken early in convalescence (13–20 days) does not seem to have any greater neutralising value than that taken later (4 months) Comparison with pooled normal serum and with serum from convalescents of long standing shows that these also contain viricidal antibodies in amounts not significantly less than those taken early in convalescence

It is possible to collect pooled convalescent serum with a neutralising value as great as that obtained by immunising horses

MEDICINE AND THE LAW

Perils of the Paddling-Pool

LAST August a boy entered a paddling pool in Bishop's Park, an attraction furnished by the Fulham borough council to simulate the seaside The pool was nowhere more than 2 feet deep The boy felt his foot make contact with something sharp, on coming out of the water he found his foot was rather seriously cut A park keeper bandaged him and he was taken to hospital The main ligament of the great toe had been severed, it was sutured and the boy made a good recovery He sued (through his father) for damages for negligence on the part of the borough council Mr Justice Greaves Lord found the defendants to have been at fault They ought to have known that, if not carefully supervised, the pool would become a trap They had given their park keepers instructions which, if carried out, would probably have averted the accident The glass was a danger of which the council ought to have known The park keeper had a rake with which he went over the pond and the heaps of sand alongside it The type of rake did not go deep enough The learned judge did not rule that the council must always provide supervision to prevent bits of glass from getting into the pond, but proper supervision could have prevented the accident, and there had not been proper supervision Another boy had been injured in the same place not long before An assistant park keeper knew of this earlier injury and, in breach of his instructions, omitted to report it further The council was responsible for the negligence of its servants There was prolonged legal argument over the responsibility for the child in the pool. Was he what the law calls an invitee, or was he merely a licensee, a person allowed to be present at his own risk? The court held that the boy was an invitee, the council had placed the paddling pool and the sand heaps as an attraction for children, and the judge came to the conclusion that he could take judicial notice of the fact that most children paddle with bare feet He awarded £50 damages to the child, and £19 10*s* 6*d* to the father as special damages for expenditure incurred in consequence of the injury Thus to the difficulty of keeping sand and water clean in these places to which children resort there is now added the problem of sifting the sand to see that no foreign substance with a sharp edge is present

The Doctor's Charges

A patient who had not paid his doctor's bill contended that the rate of charge was too high inasmuch as the doctor had less than 100 yards to travel when visiting him The plaintiff, a doctor at Turnham Green, was suing the defendant, a professional man, in the Mayor's and City of London Court for £3 3*s* for medical attendance, including six periodical visits The charge per visit was 7*s* 6*d* The defendant thought 5*s* would have been amply sufficient The registrar of the court ascertained that appendicitis was suspected. If, he remarked, the patient was cured without the expense and danger of an operation he was lucky Doctors, he explained, had to regulate their fees as nearly as possible to the social position of the patient He gave judgment for the amount claimed and added a fee ("it will be rather more than the 7*s* 6*d* which you disputed") for the attendance of the plaintiff doctor at the court that day As a pendant to these proceedings we may add the comments of a deputy county court judge in a Gloucestershire court a week or two ago Doctors' bills, he remarked, ought always to be the first to be paid, whereas they were usually the last The gratitude of patients evaporated in time, and the non payment of bills led to many inadequate excuses

VENEREAL DISEASE IN THE U S A

(FROM AN OCCASIONAL CORRESPONDENT)

A CONFERENCE on the venereal diseases was held in Washington just after Christmas at the call of Surgeon General Thomas Parran Delegates were present from 45 States, and the district of Columbia, Puerto Rico, Hawaii, and some ten foreign countries In all 900 delegates were registered and many others were present who did not register their names Both the attendance and the vigour of the discussions surpassed all expectations

The most practical proposal coming from the conference was that Congress should increase the $10,000,000 annual appropriation under title VI of the Security Act to $25,000,000 with the understanding that the main part of this difference is needed to combat syphilis The proposal was voiced by Dr A T McCormack, State health commissioner of Kentucky and president-elect of the American Public Health Association. Having pointed out the salient facts in the present situation one million new cases of syphilis contracted yearly, less than half of these treated effectively, adequate facilities for diagnosis and treatment rarely available to the afflicted person and public health facilities for control totally inadequate, Dr McCormack continued —

> "This nation has definitely embarked upon a program of social security It has determined that the hitherto under privileged and neglected shall be able to secure the comforts and necessities of life We have provided pensions for the blind, assistance for dependent children, care for the crippled, and in a hundred other ways are paying untold thousands of dollars for our previous and continuing neglect in the prevention of such diseases as syphilis The staggering price we have paid for our failure to control syphilis and similar preventable diseases is only of value in the consideration of the development of effective plans for public health prevention and control of such disasters In different communities, it has been clearly demonstrated that syphilis, like tuberculosis diphtheria typhoid fever, yellow fever and small pox, is a distinctly and definitely preventable disease In order to accomplish this high purpose, it is necessary to improve Federal, State and local administrative and service machinery to the end that prevention, early diagnosis and continuous treatment shall be available for every citizen in America needing service"

Dr J H Stokes spoke on the clinical treatment of syphilis, emphasising the importance of adhering to the continuous alternating system of treatment shown to be the most effective by the studies of the coöperative clinical group

> "The most refractory stage of early syphilis,' said Dr Stokes, "is the seropositive primary, and it is during this stage that most patients present themselves for treatment It is only by greatly increasing the amount of treatment called for in seronegative primary syphilis or in the fully developed secondary stage that the expectancy can be brought up to the general level Secondary syphilis treated by intermittent methods yields even poorer results than seropositive primary, but if treated by a continuous system, the results closely approximate the best obtained in seronegative primary syphilis"

Bismuth, in the judgment of Dr Stokes, has lefinitely established its superiority over mercury specially in the prevention of relapse Frequent Vassermann tests are needed to control treatment. A return to a strong positive after a series of negative reactions in either early or latent syphilis is a serious warning In every pregnancy the blood should be tested twice: first at the third month so that positive cases shall all receive treatment before the fifth month and secondly in the eighth month to detect the possible transmission of infection during pregnancy In the treatment of neurosyphilis Dr Stokes considers malaria the best means of inducing fever but considers there is not much to choose between fever therapy and the administration of tryparsamide.

The clinical management of gonorrhœa was discussed by Dr P S Pelouze who held that if syphilis is allowed to receive the most attention and so make the far more prevalent disease gonorrhœa appear a poor second in importance our citizency will be played a rather sorry trick. However Dr Pelouze did not minimise the difficulty of controlling gonorrhœa He admitted that no treatment known to day will quickly render the patient non contagious and that gonorrhœa can be transmitted to others so long as there is a single gonococcus present Since there are no laws to compel treatment of carriers of gonococci the field narrows to just what a medical mind can do with the mind of the infected patient. Pleasure loving American youth said the speaker might be divided into three groups: the conscientious patients, the indifferent and a large intermediate group who would follow treatment conscientiously only if someone took the trouble to make them understand the necessity The present need is for the instructors who will take this trouble

Dr Pelouze s paper was read on the first day of the conference and was open to discussion in section meetings on the second day No discussion was heard however in the section on public health administration where, if anywhere, it might have been expected The general impression seemed to be that while his point was well made it represented an ideal to aim at rather than a practical administrative policy

Dr R A. Vonderlehr assistant surgeon general in charge of venereal disease control, reported on the present activities of State health departments in this field Twenty five States have started new activities in venereal disease control as a result of subsidy already received under the Social Security Act. Sixteen States now administer their programmes through a separate division in charge of a full time officer Thirty seven States administer drugs or free treatment 21 provide dark field examination for diagnosis. There are about 1000 free pay and part pay clinics for the treatment of syphilis and gonorrhœa in the United States or approximately one clinic to every 130 000 of the population. The distribution of these clinics is uneven In the south where the high incidence of syphilis among the negroes makes clinics most desirable the supply is below the average Dr Vonderlehr s conception of an adequate programme includes: the appointment of a full time venereal disease control officer in every State department of health, a much more liberal policy with regard to the free distribution of antisyphilitic drugs the adoption of reasonable standards of efficiency by State health departments before formal recognition is given to clinics for the treatment of syphilis and gonorrhœa, and a much more liberal allotment of funds for direct expenditures in the control of the venereal diseases

IRELAND

(FROM OUR OWN CORRESPONDENT)

ROAD ACCIDENTS

Last year there were 9602 road accidents in the Irish Free State with 3932 persons injured and 205 deaths The number of deaths was slightly less than in the previous year (226) and the number of injuries slightly more (3817 in 1935) but the number of recorded accidents was more than doubled Of the accidents involving deaths 201 in number 71 were attributed to private cars 39 to motor lorries (including steam lorries and road locomotives) 27 to pedal cycles 16 to horse-drawn vehicles 9 to motor buses and coaches 11 to taxis and hackneys, 8 to motor cycles 5 to electric trams and 15 to motor vans and light commercial vehicles The number of deaths on the roads has increased slightly but with many fluctuations in the last six years, while the number of persons injured has increased with little fluctuation from 2870 in 1931 to 3932 last year

The number of fatal accidents in the Dublin metropolitan area in 1936 was 44 being 11 less than in 1935 Only one fatal accident was attributed to a pedal cyclist. The number of persons killed in the Dublin area is considerably below the average of the last six years but the number of those injured is above the average although less than in 1935

The returns for the Irish Free State further show that the most dangerous hour of the day on the roads is from 7 to 8 P.M The age incidence of deaths is interesting Of the persons killed 8 8 per cent were children under six years of age 18 1 between six and twenty 19 5 were between twenty and thirty 10 7 between thirty and forty 8 3 between forty and fifty 11 2 between fifty and sixty and 23 0 over sixty It is noteworthy that only 3 of the fatal accidents were attributed to drunkenness of a driver

THE MEDICAL RESEARCH COUNCIL

The personnel of the Medical Research Council of the Irish Free State has been completed by the appointment by the Minister for Local Government and Public Health of Dr Robert P Farnan as chairman Dr Farnan is gynæcologist to the Mater Misericordiæ Hospital Dublin and professor of obstetrics and gynæcology at University College Dublin (National University of Ireland)

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

VESICAL CALCULI IN AVITAMINOSIS

During the National Medical Week Dr Paul Fodor read a paper in which he said that he had given rats McCarrison s vitamin A free diet He has carried on the experiments much longer than any other workers in this field, waiting for the animals to die naturally With this method he has succeeded in producing vesical calculi in 90 per cent. of the rats The stones were all secondary and infectious in origin. Every animal that had received the diet had an infection of the urinary tract *Bacillus coli* could be cultivated, and the urine gradually became alkaline Assuming a lack of vitamin A as a cause Dr Fodor investigated the vitamin level in the blood but he failed to find any quantitative deviations On the other hand the condition cannot be attributed to the lack of vitamin alone; it must be due to the interaction of several factors The avitaminosis renders the animals prone to infections and the preponderantly carbohydrate diet changes the reaction of the urine and also the conditions governing the solution of its salts According to Fodor it is the protein that is of the greatest importance in the lithogenous diet

THE PYREXIAL TREATMENT OF NERVOUS AND MENTAL DISEASES

On the same occasion Dr Stephan Somogy gave account to the experiences of the Budapest neurological and psychiatric clinics in the fever treatment of mental and nervous disease in the last 12 years on more than 1000 patients They induced pyrexia in 873 instances, with malaria in 550 patients, in 135 with drugs, and in 188 with milk injections With these various methods the following results were attained with malaria, 20 per cent were cured and 24 2 per cent improved, with Neosapro vitan, 10 per cent cured and 30 per cent improved, with Pyrifer Pyrago, 8 5 per cent cured and 30 per cent improved, and with milk injections, 12 7 per cent cured and 25 per cent improved. Thus malaria therapy proved the most efficacious Somogy holds that the hyperpyrexia itself is the most important factor In the manic depressive psychosis, schizophrenia, and epilepsy there were no conclusive results In the various other diseases the following were the results obtained In tabes only some improvement in the symptoms was noticeable, chiefly in relieving the lancinating pains and the crises, in the chronic forms of epidemic encephalitis and in disseminated sclerosis the results were poor In contrast with this the method was very successful in chorea minor, general paralysis of the insane, acute trigeminal neuralgia, acute peripheral facial paralysis, and sciatica

PRESIDENTIAL ELECTION IN THE MEDICAL CHAMBER

After disputes and discussions lasting for years the Hungarian Medical Chamber has now been constituted The presidential election took place recently and Dr Tibor Verebélyim, director of the First Surgical Clinic of the University of Budapest, has been elected, with Dr Ladislaus Csiky as vice president The council of the Chamber was elected by the representatives of the Budapest and country chambers Altogether 81 country electors sent postal votes, while the 52 Budapest electors voted personally The number of electors is always adjusted to the number of members, which is much fairer than the system prevailing in Rumania, where the medical chamber has just been introduced There the presidents of the county chambers elect the national president, so that a president of a county with only 25 members has just as much influence as one who represents a chamber with a 1000 or more

CHILD WELFARE IN HUNGARY

During the week also Prof Kornel Scholtz, Minister of Public Welfare, gave some elaborate statistics, showing that in Hungary the infant mortality in the last ten years has fallen considerably *In the new born (0–6 days)*, however, the *position* is not so favourable, emphasising the need for the more intense development of prenatal care The great fluctuation in the mortality rate of infants in the first three months is mainly attributable to summer diarrhœa, the curve of which is almost parallel with that of the maximum summer temperature Another cause is influenza, in the four influenza years of the last decade 54,913 more of the population have died than in the intervening epidemic free years, and 8600 of these were infants The death rate of children from 1–14 has been almost halved since 1920 This great improvement was due to the diminution of deaths from acute infectious diseases It is striking that while the death rate of respiratory diseases is very considerably diminished in all age groups, in tuberculosis of other organs it rose considerably at all ages A considerable improvement is noticeable also in the death rate of other groups of diseases The drop in deaths due to "congenital debility" of infants is clearly due to better medical services In this respect the chief aims of Hungarian public health are to develop better prenatal care, to augment the hospital accommodation for children suffering from acute infections, and to check diphtheria by the wider use of protective inoculation For combating tuberculosis in children arrangements are being made for the adoption of Calmette's method Finally, special care is to be taken in improving nutrition, which in some regions leaves very much to be desired, both qualitatively and quantitatively

DEATHS IN THE SERVICES

Lieut -Colonel **Francis Alexander Caron Scrimger** V C who died on Feb 13th at Montreal was the younger son of John Scrimger principal of the Presbyterian College Montreal He served in the European War as medical officer with the 14th Battalion, Royal Montreal Regiment to which he was attached from the Canadian Army Medical Service and when a captain he won the V C on April 25th 1915 for his gallantry in carrying wounded men from an advanced dressing station near Ypres which was being demolished by shell fire Later he became assistant professor in surgery at McGill University and surgeon to the Royal Victoria Hospital Montreal his special interest being thoracic surgery Colonel Scrimger married in 1918 Ellen E Carpenter late C.A.M.C and leaves a son and three daughters. He was 57 years of age

Colonel **John Maxwell Gover**, D.S O who died on Feb 11th at Nevern-square London at the age of 69 was educated at Durham University and St Bartholomew s Hospital and qualified M.B B S Durh in 1898 After house appointments at the Royal Infirmary Newcastle and the Brompton Hospital he was appointed assistant demonstrator in anatomy and physiology at the Durham College of Medicine He joined the Territorial Army and became assistant director of medical services of the 50th (Northumbrian) Division with the rank of colonel At the outbreak of the European War he was assistant surgeon to the Fleming Memorial Hospital he served from 1914 on was mentioned in dispatches, and received the D S O in 1918

PANEL AND CONTRACT PRACTICE

Medicines Urgently Required

Most insurance practitioners are aware that under the Terms of Service they are required to supply and not merely to prescribe drugs or appliances which are needed for immediate administration or application or for use before a supply can conveniently be obtained from the chemist In England and Wales the yearly rate of payment for this task is usually 1*s* 3*d* per hundred persons on the list but in some areas where the liability for emergency dressings is greater a rate of 2*s* 6*d* may be sanctioned or payment may be made at a flat rate for each occasion on which dressings are supplied in an emergency Prescriptions marked urgent which carry a double dispensing fee may be issued after the chemists shops are closed, but only if it is essential that the drug or appliance should be supplied the same day and if there is a resident chemist reasonably accessible who will make it up If there is no such chemist it rests with the doctor to supply the drug or appliance himself

An insurance practitioner recently complained that a chemist had refused to dispense the medicine he prescribed On investigation it appeared that at about 10 P.M. on Christmas Day a prescription for mist camph co of the National Formulary was issued and that a representative of the insured person called at the private house of the chemist and asked him to dispense it Not unnaturally the chemist declined The relatives then discovered the private address of another chemist who was persuaded to go to his shop and dispense the mixture shortly before midnight He in his turn was not unnaturally annoyed and informed the insurance committee accordingly And so because a practitioner had failed to make himself acquainted with his Terms of Service the patient and her friends as well as both chemists were put to inconvenience late at night apart from the unnecessary work thrown upon the insurance committee in dealing with the complaint he raised

Medical Insurance Practice

Insurance practitioners have lately received copies of the Medical Benefit Regulations 1936 which include their Terms of Service but it is doubtful whether many have the time to study these regulations exhaustively It is opportune therefore that the fourth edition of Medical Insurance Practice the excellent handbook by R. W Harris and Leonard Shoeten Sack should have been issued almost concurrently The many alterations in the regulations since 1920 when the previous edition was issued have made revision imperative and now at an almost nominal price practitioners may obtain an authoritative explanation of their duties and responsibilities written mainly in the direct second person reference to which may well settle in a minute or two those nasty little problems that are likely to arise at any time

Take for example spinal jackets which may now be prescribed when required for treatment of fractures dislocations, or diseases of the spine A footnote (p 85) points out that it has been held that a spinal jacket is necessary and required in connexion with treatment (and the original cost and cost of periodical repair may therefore be debited to the drug fund) if it is likely to restore or maintain an insured person s capacity for work but not if it is used for improving the appearance of the patient —e.g to hide a hump on the upper half of the spine

The many appendices contain information which is invaluable; such as extracts from the report of the advisory committee on the definition of drugs for the purposes of medical benefit Reference to the list of never a drug might save the annoyance of an inevitable surcharge The book is well indexed, and much ingenuity must have been expended in the compilation of this all important section The preface to the first edition addressed the book to the busy general practitioner and added that the authors while excluding matters too remote to be of interest to him had tried to avoid leaving unanswered any question arising in his daily insurance work on which he is likely to seek information in its pages Their exhaustive revision brings the book to a standard if anything higher than that of the earlier editions It is obtainable from the British Medical Association at 2*s* post free

Fellowship of Medicine and Post-Graduate Medical Association.—A special course in physiology and anatomy for the primary F.R.C S examination will be held on Mondays Wednesdays and Fridays at 5 15 P.M at the Infants Hospital (Feb 22nd to May 24th) A course in proctology will be given at St Mark s Hospital (March 1st to 6th); in orthopædics at the Royal National Orthopædic Hospital (March 8th to 20th) in infants diseases for candidates for the D C H at the Infants Hospital (March 8th to 13th) in urology at All Saints Hospital (March 20th and 21st) M R C P courses will be held in chest diseases at the Brompton Hospital (twice weekly at 5 P.M Feb 22nd to March 20th); in chest and heart diseases at the Royal Chest Hospital (Mondays, Wednesdays and Fridays at 8 P.M March 1st to 20th); in neurology at the West End Hospital for Nervous Diseases (afternoons, March 8th to 20th) A mock trial of a motorist accused of being under the influence of drink will be held on Thursday March 11th at 8 30 P.M Admission will be by ticket only and full particulars can be obtained from the secretary of the fellowship 1 Wimpole-street W

CORRESPONDENCE

SURGICAL TREATMENT OF CARDIAC ISCHÆMIA

To the Editor of THE LANCET

SIR,—Mr O'Shaughnessy's lecture published in your issue of Jan 23rd is evidence of the admirable work done at the recently established cardiovascular clinic at Lambeth Hospital, and also at the Buckston Browne Farm. He is to be congratulated on his evidently remarkable surgical technique, as well as on the clarity with which he describes his operation and its results, and above all he is to be congratulated on being so scrupulously careful not to claim as yet to get brilliant clinical post-operative results, but rather to content himself with the demonstration that cardio-omentopexy is in his hands "a feasible operation attended with a low immediate mortality."

It is to be hoped that others may be equally cautious in their choice of cases for omentopexy, and in their claims for a successful result. For it is clear that this operation is tempting progressive surgeons. I note that cases of omentopexy were shown at the clinical section of the Royal Society of Medicine last week. The more unstable of our anginal patients already begin to demand surgical treatment. Finally, that astute and up to date journalist "Dr Harpole," has included omentopexy in his "Surgeon's Diary." In a word, these and many other portents indicate that we are in for a spate of omentopexy. But before the flood descends upon us and perhaps carries away hastily improvised barriers of clinical experience and judgment, there are a few observations which I would like to make. And if these observations seem to be somewhat elementary in nature I do not seek to be excused. For is it not true that in these days of elaborate investigations and treatment, elementary considerations are apt to be forgotten?

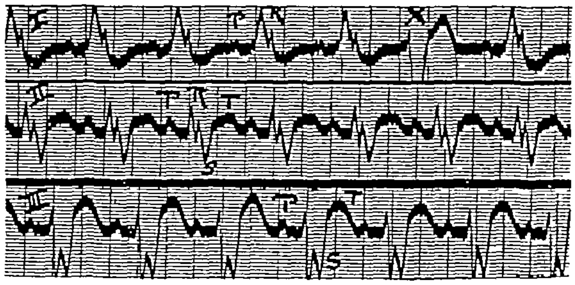
Lord Dawson has epitomised the problem in the final paragraph of his introduction to Mr O'Shaughnessy's lecture:—

> "It follows therefore that in a considerable coronary occlusion collateral circulation must eventuate if the myocardium is to be saved. *Such a compensatory circulation can form of itself*: where it does not do so, the use of surgical means to establish it is essentially reasonable and its prospect should be good in carefully selected cases *provided the capillary bed itself is not too degenerate to profit by a renewed arterial supply*."

I would like particularly to emphasise those words of Lord Dawson which I have italicised. Let us never forget that "a compensatory circulation can form of itself," and that consequently it is possible, indeed probable that some cases of cardiac ischæmia may recover in spite of, and not because of, the surgeon.

Angina pectoris is a much maligned disease. We never open a newspaper without reading of the sudden cardiac death of some distinguished individual. Thus daily it is hammered into our minds that angina is a very dangerous condition. We tend to forget that if an anginal patient lives within his limits and obeys a few very simple rules he often leads quite an active and useful life for many years. He may indeed even lose his angina and die of something else. Of James Mackenzie's 214 fatal cases,[1] for example, approximately one half survived for five years, and 44 of them lived for more than ten years—not a bad record when we find that 77 of the 106 patients who survived the five year period were already over sixty years of age at the onset of their angina! To quote Mackenzie again, "The ages at which death occurs (from angina) do not differ materially from the average at which death occurs from disease in general"—a somewhat obscure remark, the interpretation of which would seem to be that angina does not materially affect the expectation of life.

The names of distinguished members of our own profession who have done splendid work during long periods of time, though suffering from angina, leap to the mind at once. One wonders had these men been subjected to omentopexy and survived, would they have been rendered more efficient? One of my friends has suffered from angina for eighteen years. Some years ago he had a coronary occlusion. He has led an exceedingly busy professional life and is still working at the age of seventy five, and is no doubt congratulating himself that omentopexy was not the vogue eighteen years ago.



Electrocardiogram of Mr A in 1930. Bundle branch block and one ectopic ventricular beat (X).

Many of us can recall spectacular recoveries from chronic heart failure of arterio sclerotic origin. Another of my friends had cardiac asthma in 1934, with a tension of 240/140 and alternation. In 1935 he had an alarming attack of acute pulmonary œdema, and later on a transient hemiplegia. From October, 1935, till September, 1936, he was waterlogged, and his intense dyspnœa could be controlled only by morphia. A few weeks ago he came up from the country and had lunch with me, free from œdema, and sleeping peacefully at night without any sort of sedative. What a triumph he would have been for omentopexy had this been performed last spring (and had he survived it!)

One more example:—

Mr A, aged 54, was seen with Dr Brebner Scott in April, 1930. He gave a history of angina of effort and of gasping attacks at night. His blood pressure was 200/130. In August of the same year he had a coronary thrombosis after which he developed a bundle branch block (vide electrocardiogram) and became waterlogged, with paroxysmal nocturnal dyspnœa. He was nine months in bed, and for some four months his condition appeared to be quite hopeless. In March, 1931, however, he was up for half the day and in May, 1931, he returned to his business at Covent Garden getting up at 5 A.M. and working till 4 P.M. without any œdema. *He worked till September, 1932,* when he broke down again, after influenza. In February, 1933 he was still up and about and free from œdema. He died of chronic cardiac failure in King's College Hospital in May, 1934. Again what a surgical triumph he would have been if operated upon successfully, in February, 1931!

When one reflects on cases such as these—and any clinician of experience could quote others like them—one feels that after omentopexy, as in many other conditions the vis medicatrix naturæ may sometimes be responsible for a successful result

---

[1] Mackenzie, J. (1923) Angina Pectoris, London.

At the same time there is no doubt that a case has been made out for this operation The difficulty is of course the decision as to when to operate One hesitates to advocate surgery so long as there is a reasonable prospect of the heart establishing its own collateral circulation and one must not wait until the capillary bed is in Lord Dawson's words too degenerate to profit We admire the surgical skill which restored the sprinting power to a greyhound a branch of whose coronary circulation had been ligated But this experiment would have been more convincing as an argument for omentopexy in man had the greyhound been ten or more years old at the time of the operation

Finally another depressing thought why is the Talma Morrison operation apparently extinct? *Pace* Prof Grey Turner I really cannot believe that it has been abandoned only because the patients will not be persuaded to become abstainers!

I am Sir yours faithfully

Montagu-square W., Feb 10th MAURICE CASSIDY

OXYGEN TENTS

To the Editor of THE LANCET

SIR,—Rather over a year ago the British Red Cross Society deposited in each of the twelve teaching hospitals of London an oxygen tent of the Guy's Hospital pattern so that a wide experience of this method of treatment might be gained We who were appointed as a small medical advisory committee would in the first place like to thank the Society for their public-spirited action, the value of which is indicated by the reports received from the various hospitals All these reports emphasise the value of the oxygen tent in the treatment of grave cases of anoxæmia One of these reports that from St Bartholomew's by Dr D C Reavell was published in your issue of August 1st and we may quote his statement that from the clinical point of view the results were better than with any previous method of oxygen administration and patients were kept in the tent continuously for periods up to 12 days without any difficulty A report from another hospital emphasised its value in the treatment of children suffering from bronchiolitis or bronchopneumonia once in the oxygen tent these small children appear to resent being taken out[1] and there is no question that this apparatus is highly successful and almost the only method of achieving the results attempted. In another hospital a child who had had one lung removed by operation was in the tent for a considerable time and the treatment proved of the greatest benefit Another report describes a girl aged 11 months, whose colour improved and who appeared much happier within about half an hour of entering the tent; the pulse rate fell and the respiration rate also fell and the child made a good recovery Another patient aged 65 with chronic bronchitis and asthma strongly objected to the tent when it was first used for him but was later readmitted to hospital very cyanosed and dyspnœic and almost moribund This time he felt so much better in the tent that he willingly persisted with it and made a remarkable recovery after some four days Later he did not remember ever having been in the tent at all It is perhaps unnecessary to multiply instances of the beneficial effect of a treatment which merely ensures that a patient is getting a known high percentage of oxygen

When the details of managing the patient are considered it is perhaps natural that there should be some difference of opinion Dr Reavell stated that the tent could be set up and new people instructed in its management in two hours when once running no undue call was made upon the house physician and apart from general supervision by the house physician it could be managed entirely by the ward clerks and nurses when once the sister and nurses had become accustomed to the tent it was little or no hindrance to general nursing Another report says that the oxygen control presents no difficulty and a concentration of 50 per cent could easily be obtained and maintained The gas analyses of which oxygen is the most important can easily be carried out and can soon be taught to sisters and nurses In one hospital it was noted that the tent could be used satisfactorily for surgical cases but in another hospital the nursing of these cases in the tent was found to be extremely difficult Several reports emphasised the difficulty of controlling delirious and fractious patients in the tent This difficulty is common to all methods of oxygen administration

Some criticism of the details of the manufacture of the tent were expressed but this is perhaps not surprising considering that it was the first time that this particular type of tent had been made up in quantity in this country and the firm employed had had no previous experience of this kind of work The chief criticism was the flimsiness of the material so that a stronger and more substantial material is now being used in all the tents that are being made at present

The Red Cross Society offered the tent to the hospitals for purchase at a little under half their original cost and seven of the hospitals accepted this offer It may perhaps cause surprise that this offer was not accepted by five of the hospitals but in four cases the refusals are thought to be due to certain technical imperfections in the tent or to a preference for a tent of another type or some simpler method In the remaining hospital the patients who had been ill enough to require this treatment were so few that it was felt that for the time being a tent could be hired when desired and that an improved model might be forthcoming later

A final word may be said about the action taken by the London County Council which controls a very large number of beds For about a year now they have had twelve tents in operation and they are hoping to increase the number so that each general hospital and each fever hospital will have at least one tent

In our previous letter we stated that arrangements had been made by one of us to send a tent to any part of the country at the request of any medical man and that a physicist not medically qualified would accompany the tent The demands on this Oxygen Tent Service" have steadily increased during the last year so that it has now been possible for it to launch out on its own account as an independent concern Applications should now be made to T W Adams A Inst P Oxygen Tent Service 33 Devonshire-street W 1 Telephone No: Welbeck 2003 and at night Gerrards Cross 1103 This service which supplies British made tents together with the two other services in London which supply American tent should be sufficient to meet all the demands for this particular type of treatment at the present time —We are Sir yours faithfully

THE SINCLAIR FOOT-PIECE

To the Editor of THE LANCET

SIR,—I have read with appreciation the lecture by Mr Salisbury Woods in your issue of Feb 6th on progress in the treatment of factures As one of the surgeons who worked for a time under the direction of Major Sinclair during the war, and who has followed his treatment of fractures with the greatest interest since, I feel that I must correct the reference made to the Sinclair foot-piece This foot-piece was never meant to sustain a tractile force greater than 4 lb When properly applied the strips of adhesive material fixing the Sinclair foot piece do *not* overlap on the dorsum of the foot, and the whole of the apparatus would be pulled off with a weight much exceeding 4 lb The function of the foot piece was mainly to control rotation of the foot and not to be a point for the application of weight extension to control shortening in the fractured femur It was, in fact, only an adjunct to skin traction applied to the thigh I have not seen a case of sloughing of the skin following the use of this foot piece for the purpose for which it was designed I am, Sir, yours faithfully,

London W Feb 12th H ERNEST GRIFFITHS

MEDICAL PRIVILEGE

To the Editor of THE LANCET

SIR,—May I thank you for your very helpful and sympathetic leading article dealing with my Bill on this subject, and at the same time make some comments upon the incident Both the Bill of 1927 and the recent one were drawn by a skilled legal Parliamentary draftsman The Bill of 1927, as I stated in my letter (Feb 6th, p 349), was supported by five eminent lawyers who actually added their names to my Bill The recent Bill differed from the earlier one in two particulars only it extended the operation of the Bill beyond the class of venereal diseases to which the 1927 Bill was restricted, and it added clauses providing a further safeguard against abuse Both the Bill of 1927 and the recent Bill were "passed" by Lord Atkin The 'legal snags" discovered by the Solicitor General seem to have escaped the observation of the very competent authorities I have named

Two reasons made me extend the operation of the Bill (i) As I explained in my letter to you a Bill restricted to venereal diseases would fail in its purpose inasmuch as any party pleading its protection would be at once stigmatised as a victim of venereal disease (ii) Protection of medical confidences is necessary in other branches of practice For example, certificates given by medical officers of health in the case of stillborn infants have hitherto been regarded as confidential, but in a recent case the doctor was compelled to disclose the cause of the death of the child, which conveyed a reflection upon the parents, again the case history confidentially imparted and entered upon the cards of panel patients by the doctor is not protected from revelation in a court of law In the Scottish Maternity Bill now before Parliament proper stress is laid upon the supreme importance for reducing maternal mortality of ante natal observation of the pregnant woman Maternal mortality is probably highest in the young unmarried mother and it is surely foolishly short-sighted to withhold from this class of case the most explicit assurance that their confidence will be respected, early consultation, which is one of the chief purposes of the Bill would be grievously hampered but for the complete trust reposed by the patient in the doctor respecting her professional confidences

In his defence of the monopoly by solicitors of professional secrecy as contrasted with the absence of privilege for the no less important confidences of the doctor and the priest, the Solicitor-General used the curious argument that solicitors enjoy this privilege because it has been "erected by the custom of the law," and that it would be difficult to put into statutory form the claims for similar privilege by the doctor and the priest

The perfectly indefensible and in its results widely mischievous refusal of privilege for medical confidences is producing chaos in the administration of the law I have knowledge of recent cases in which judges imbued with the obligation of the medical practitioner to preserve secrecy (as was evinced for example by Mr Justice Charles in the instance quoted in your leader) have excused the medical practitioner who has pleaded that honourable obligation from giving evidence Were a doctor or a priest to refuse to betray professional confidences and to suffer imprisonment for doing so there can be little doubt that public opinion would be outraged and would demand alteration of the law When the law is so clearly in conflict with public opinion it is surely better to alter it by orderly Parliamentary procedure rather than in response to an explosion of resentment in an individual case

I am, Sir, yours faithfully,

House of Commons Feb 15th E GRAHAM LITTLE

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR

To the Editor of THE LANCET

SIR,—Mr E T Bailey's instrument for introducing a Smith Petersen nail, described in your last issue, has given us a simple method of placing the nail with accuracy along the femoral neck I cannot, however, accept the statement that the instrument "obviates the necessity for calculations or for a lateral X ray during operation " Mr Bailey does not specify the type of femoral neck fracture he treats by his technique I will confine my remarks to the medial type of fracture, for the lateral and per trochanteric types always heal well without nail immobilisation

All extra articular operations are dependent for their success upon the accuracy of reduction of the fracture and the maintenance of this reduction until the fragments are immobilised by the nail The steps of the operation must be continuously under radiological control until the final immobilisation by the nail in the reduced position is achieved No instrument can replace this X ray control I have no doubt that the technique advised by Mr Bailey can give some good results, but these days we are most concerned in lessening the percentage of unsatisfactory results, and I feel that in advising a technique that replaces close radiological control Mr Bailey is advocating a retrograde step

Not all fractures of the medial type are reducible by traction in a Thomas splint I agree that sometimes by this method alone an accurate reduction is obtained It should be the routine method of preliminary treatment, the patient is made comfortable, nursing is easier, and it gives a period during which the patient can be investigated and the general condition improved

But there remains still a group of patients in whom accurate reduction has not been attained Most authorities are agreed that for this group there can be no routine manipulative reduction, simply because the displacement of the fragments is not constant

The manipulations necessary will be governed by the deformity remaining and the deformity is recognised only by radiograms taken in two planes. It seems wiser to carry out these manipulations on an orthopædic table instead of the complete bed procedure. With such a table the reduced fracture can be securely fixed and X ray control is greatly facilitated. In introducing the nail, unless steps are taken to prevent it the oncoming nail may displace the head fragment from its position on the neck; this is most apt to occur in the subcapital type of fracture. This displacement may not be recognised in the antero-posterior film but is readily seen in the lateral view. Accordingly X ray control must be continued until the operation is completed.

All of us with experience in this operation are familiar with its unexpected difficulties, difficulties only surmounted by planning on clear radiograms as the operation proceeds. Only by a technique allowing the fewest errors can the percentage of unsatisfactory results be lessened. The operation may sometimes be tedious to the surgeon, but under local anæsthesia it is quite a safe procedure even in the very elderly.

I am, Sir, yours faithfully,
WILLIAM GISSANE.

St. James' Hospital, London, S.W., Feb. 11th.

ARTIFICIAL PNEUMOTHORAX ON STATISTICAL TRIAL

To the Editor of THE LANCET

SIR,—Your annotation in last week's issue on the work of the pneumothorax subcommittee of the Joint Tuberculosis Council raises the whole question of the applicability of statistics to clinical problems. In the investigation you describe a committee of experts spent four years in the classification and follow-up of a very large number of patients treated by artificial pneumothorax and compared their fate group by group with control material which was admittedly not strictly comparable. The result was disappointingly inconclusive.

Needless to say, it would be a good thing to have statistical backing to clinical judgment as it is difficult for anyone who practises a special form of therapy not to be prejudiced in favour of the belief that his patients are better so treated than left alone. Even allowing for a bias of this nature, clinicians of experience are so unanimous in believing pneumothorax treatment to be of great value in suitable cases that it is worth while examining more closely the discrepancy between clinician and statistician. The cause of error does not need prolonged search; it lies in the fact that the control group consists of patients with a substantially better prognosis treated conservatively than the A.P. group.

Until recently pneumothorax was rarely tried except in patients who failed to improve with several months of sanatorium treatment, and failure to respond to treatment obviously indicates a worse prognosis than a good response. To this group may now be added a relatively small group of patients in whom pneumothorax is tried without delay, as experience has taught us that their prognosis will be much improved thereby.

Now the fault of the statistician in this inquiry is that he concentrates on the anatomical extent of the lesion, number of lobes affected, &c., and not on the direction in which the disease is progressing while the patient is under treatment. A fibrotic scarcely active lesion of one lobe in which the patient has almost established a condition of *symbiosis* with his bacilli is classified in the same group as a tuberculous lobar pneumonia. The first patient will be treated conservatively, and the second will have a pneumothorax tried with the knowledge that therein lies practically the only chance of recovery, and that this is by no means good owing to the tendency of this type of disease to spread whatever treatment is applied.

The final impression which remains after reading the report is that the position of pneumothorax remains as it was before. If anything has been tried and found inadequate it is the application of the statistical method to this particular clinical problem. One feels that the investigators have been thorough and dispassionate, but that the inherent difficulties of the problem have unfortunately prevented their achievement from being of the high value which the quality of their work merited.

I am, Sir, yours faithfully,
Harley-street, W., Feb. 15th. ANDREW MORLAND.

ANOREXIA NERVOSA

To the Editor of THE LANCET

SIR,—I was much interested in Dr. J. H. Sheldon's article on anorexia nervosa in your last issue and am impressed by his suggestion that we are dealing with a functional form of Simmonds's disease of psychological origin. In the same way I believe many cases labelled Fröhlich's syndrome are really instances of a temporary pre-pubertal obesity due to a functional delay in the development of the pituitary. I can corroborate from my own experience that anorexia nervosa is often preceded by obesity, and that being teased about this (powerfully aided by the fashionable cult of slimness) is frequently the incentive which starts the process of self-starvation. The subjects of this condition are generally feminine Peter Pans who are afraid of growing up, and now that we realise the close association between the emotional centres in the diencephalon and the pituitary gland, we can understand how the emotional state may inhibit pituitary function.

But I am still puzzled by the blood-sugar curves. Dr. Sheldon's 1st and 5th cases show practically no rise after 50 grammes of dextrose, whereas simple fasting causes the curve to approximate to the diabetic type. A flat curve indicates rapid absorption of dextrose, yet these patients do not put on weight in consequence. Different observers give very varying descriptions of the blood sugar in Simmonds's disease. H. Zondek states that it was usually within normal limits in his cases. Wolf states that sugar tolerance is diminished in Simmonds's disease, resulting at times in glycosuria. Goldzieher on the other hand considers a constantly low blood sugar and a considerable increase in sugar tolerance typical of every hypopituitary case, whether of the obese or lean type. Wilder has seen hypoglycæmic *crises* which were readily relieved by sugar. We should expect Houssay's diabetogenic hormone to be diminished with lessened anterior pituitary functions, so that a lowered blood-sugar curve is perhaps to be anticipated from the unopposed *action of insulin*. Several observers describe insulin sensitivity, but in my experience these patients put on weight more quickly under appropriate psychological treatment if also given insulin well covered by dextrose. Even dextrose alone is helpful. It would therefore appear that the mechanism for storing carbohydrate may be present even in excess of normal if only it is provided with adequate fuel. It is also possible that the loss of the normal adrenotropic action of the pituitary leads to a functional adrenal insufficiency. Demole (*Presse* *medicale*, 1936, 44, 543) gives as its characteristic features (1) asthenia without pigmentation or much lowering of the blood pressure, (2) chronic if vague digestive disturbances, (3) fasting hypoglycæmia which is converted into hyperglycæmia by the injection of cortical extract This third point might prove to be of diagnostic value

Dr Sheldon's paper certainly provides food for reflection on the influence of the emotional state on endocrine functions It is the more important because anorexia nervosa seems to be on the increase This I attribute to the increasing frequency of tension between mother and adolescent daughter, the fashionable fear of obesity, and the fear of going out into a world fiercely competitive in work and games alike I am, Sir, yours faithfully,

W LANGDON-BROWN

Cavendish square W Feb 15th

To the Editor of THE LANCET

SIR,—Many will agree with Dr Sheldon that this disease is often accompanied by changes indicative of pituitary dysfunction At the Maudsley Hospital biochemical and metabolic investigation of cases of anorexia nervosa have been carried out independently during the past year These appear to confirm many of Dr Sheldon's views The publication of the results have been delayed so as to compare them, if possible, with a series of control cases from patients having other types of psychological disorder and weight disturbance

The whole problem of loss of weight in illness supposed to be psychologically determined is of extreme interest and urgently requires investigation, work done here, for instance, has shown that many of these patients make only slow improvement even when taking a high calorie diet Anorexia nervosa provides an exceptional chance of studying the complicated interrelations of metabolic and psychological changes It is to be hoped that Dr Sheldon's paper will stimulate a very wide interest in the various aspects of this syndrome, if so, it may soon be possible to deduce observations applicable to its more satisfactory treatment

We are, Sir, yours faithfully,

WILLIAM SARGANT,
W S MACLAY

The Maudsley Hospital, Denmark Hill S.E Feb 13th

TUBERCULOUS ABDOMINAL GLANDS

To the Editor of THE LANCET

SIR,—May I now reply to some of the points raised by Dr Pask and Dr Wilkinson? The proportion of children and young persons enjoying the fresh air, sunshine, and good food in institutions who require surgical intervention is not known to me When the diagnosis is positive operation in such a patient may be avoided with an easier mind Those operated on in our series were mostly workers, many of them farm labourers, who had been well fed and had had an open air life, but not much rest Symptoms had generally been insufficient to prevent work until admission Most were actual or potential emergencies and no patient was operated on merely to make a diagnosis The tendency to the formation of adhesions in these patients is high and such an operation would not assist natural cure There is no doubt that judgment may decide in favour of operation to clear a doubtful case when a ward is receiving A waiting list amounting to double the number of beds and the knowledge that the patient will be returned if sent out unfit for work are factors which are apt to weigh The number of institutional beds available for long continued cases is not large if all doubtful cases are to be treated The serious mortality *from abdominal tuberculosis in the early years* of life leaves a type of patient with a tried resistance, which helped by restful conditions and good food, improves with time

The Registrar General's reports show a steady reduction in the annual mortality from abdominal tuberculosis in England and Wales to nearly one sixth between 1910 and 1935 (4345 persons in 1910 to 750 in 1935), presumably due to cleaner milk The corresponding mortality from obstruction has remained throughout at some 2500 persons, with a recent tendency to rise The varieties are not officially distinguished, but the commonest causes of acute obstruction in children and young adults are bands and adhesions The operative mortality in expert hands is very high

Of the 10 fatal cases in our paper 3 deaths were due to the operation, 3 to strangulation, 1 to appendicitis, 1 to hemiplegia (two years), and 2 to phthisis (three years and two years) Of 10 patients with acute and 3 with subacute obstruction, 10 recovered Ten of the reoperation cases had been initially operated on elsewhere for acute symptoms We managed to retain all our own failures in this respect, hence the large proportion There was one fistula case successfully dealt with by resection of the gut and attached caseous gland, before emaciation became severe There were two keloid scars which subsided without radiation, three ventral hernias were all successfully operated on and cured Carson pointed out that operation in caseous cases must be evaluated on the grounds of necessity not of choice

Future prevention will depend on providing clean milk at a cheap rate, on dealing with such archaic anomalies as sweeping up the dust in the tube railways instead of extracting it, on fixing the dust in railway tunnels by suitable spraying, and on greatly reducing the sojourn of the population in the tubes by having universal "zone" fares and the completed tickets available on the automatic machines Phthisical persons and carriers of other infectious diseases should be individually isolated, not herded together I am, Sir, yours faithfully,

London W Feb 15th G H COLT

DEFOE'S STORY OF THE PLAGUE

To the Editor of THE LANCET

SIR,—If a mere layman is allowed to differ from the grave and reverend seigneurs who have contributed the series Grains and Scruples may I be permitted to question the accuracy of the statement on p 1543 of your Dec 26th issue as to Daniel Defoe's story of the Great Plague being merely a journalistic account of an event of which he could know nothing, he being then, according to your contributor, a baby of two or so Though this idea was at one time held, more recent researches suggest otherwise G A Aitken, a recognised authority, gives his birth as some time in 1659 Therefore he would be six at the time of the Plague Six years of age at that period would make Defoe—who also must have been a precocious urchin—quite able to absorb lasting impressions of such a tragic time, and it would certainly seem on this evidence that his story of the Plague may be regarded as built on a foundation of personal recollections even though these are added to by consultation of the documents available

I am, Sir, yours faithfully,

Mulberry close S W Feb 10th E J HOLLAND

ENDOMETRIOMA OF THE VULVA

To the Editor of THE LANCET

SIR,—No single theory will explain the origin of all endometrial tumours of the vulva. Samson s implantation theory appears to account for such cases as that reported to the North of England Obstetrical and Gynæcological Society on Oct 30th by Mr T N A Jeffcoate (*Lancet* 1936 2 1336) in which it was most likely that endometrial cells from the menstrual blood were implanted into the raw surface of a cavity formed by the rupture of a post operative wound Other cases, occurring in women who have undergone no previous operative measures with no history of injury to the vulva and in the absence of any hernial sac can only be explained as developmental abnormalities

In the human embryo at the third month the inguinal fold can be demonstrated as an outgrowth from the Wolffian ridge The point of the outgrowth is the junction of the uterine and Fallopian segments of the Müllerian ducts within the Wolffian ridge. In the inguinal fold the round ligament of the uterus is developed and it is presumed that to use a simile of Comyns Berkeley during the building of the female genital house some chips of the Müllerian structure are carried away by the developing round ligament to find a resting place in the part of the labium in which this ligament becomes dispersed and that these chips become activated during the reproductive period of life perhaps under the influence of œstrin. In support of this explanation may be mentioned other tumours—to wit dermoid cysts of the floor of the mouth and teratoid tumours of the testicle—which rarely become clinically evident before puberty

The comparative rarity of endometrial tumours of the vulva, of whatever origin is shown by the fact that Jeffcoate, before reporting his case was able to find only six others on record.

CASE REPORT

Mrs A of Hog Eye Arkansas nullipara aged 30 first consulted us in regard to a painful swelling of one year s duration in the right labium majus on Feb 1st 1936 She described it as feeling as though there were a cockleburr under the skin which became more painful during the latter half of her menstrual period and partially subsided during the following week She believed it was a hernia, for which she had been wearing a truss for two years

On examination the inguinal region was normal The upper half of the right labium was swollen and at the extreme upper end could be felt a firm tumour approximately almond-sized Bimanual examination of the pelvic organs revealed no abnormality and there had been no change in the menstrual habit which was 28/5 Subsequent examinations at appropriate intervals confirmed the patient s history of periodicity A diagnosis of endometrioma was made and the nature of the tumour explained to the patient who readily consented to its removal for histological study Operation was performed at the Elizabeth Hospital Prairie Grove Ark on March 10th under general anæsthesia to permit of direct inspection of the right inguinal canal and abdominal inguinal ring These were seen to be normal, the incision was closed and the tumour then removed through a separate incision into the labium Recovery was uneventful and there has been complete freedom from symptoms up to the present time The truss has been abandoned

The tumour was submitted to Dr J H Fisher professor of pathology in the University of Western Ontario London Canada to whom we are indebted for his kind permission to publish his report which is as follows : Specimen is roughly spherical measuring 2 cm in diameter The outer surface presents a roughened appearance with tags of fibrous and fatty tissue attached On section the cut surface is firm greyish white with darker points and small areas scattered through it The sections show many dilated glands composed of tall columnar epithelium and surrounded by typical endometrial stroma These glands strongly resemble those of the uterine endometrium Most of them contain blood and fragmented granular material The glandular structures are embedded in a rather dense fibrous tissue with a small amount of fat

Pathological diagnosis : endometriosis

We are Sir yours faithfully

TRANSIT OF PREGNANT WOMEN BY AIR

To the Editor of THE LANCET

SIR,—The question of the transit of pregnant women by aeroplanes has come up for consideration and is one of importance to the medical profession as well as to the general public Several factors are involved, such as the distance to be travelled and the facilities which exist for medical aid at the landing-grounds as well as the condition of the patient herself The rules formulated would presumably differ for those flying within European limits from those flying across Africa or Asia or to Australia and tentatively one might suggest a limit of one clear month from the expected date of delivery in the former and two months for the long-distance passengers I should be grateful to members of the profession who would give their views on this question either in the columns of this journal or in private correspondence

HUNTERIAN FESTIVAL DINNER

THE biennial dinner of the Royal College of Surgeons of England was served in the library of the College on Feb 15th under the happiest auspices Immediately overhead was in progress the reconstruction of the three upper floors of the College to make a new and adequate institute of surgical research and incidentally completing Sir Charles Barry s beautiful facade The company over which Sir CUTHBERT WALLACE presided included five Hunterian trustees the treasurers of the four Inns of Court, eight masters of City Companies and the medical directors of the three Defence Forces Sir CHARLES GORDON WATSON who toasted The Guests paid special attention to Lord Russell of Killowen and Sir Plunket Barton who were sitting by him but the real guest of the evening was John Hunter whose memory was drunk in reverent silence

I like ' said Sir Cuthbert to think about three characteristics of the man First there was his curiosity This word is now perhaps of ill favour but in its best sense it describes well Hunter s childlike desire to find out how things work and caused him if not to originate to improve and amplify the experimental method Secondly there was his diligence He was a whole time worker though not in the modern sense. Hunter had a large practice the gain from which he devoted to paying for his researches He was late and early in his workroom and left himself but four hours for sleep Then there was his courage when stricken with a terrifying disease Hunter calmly continued his work and made himself an object of his own study "

And having said this Sir Cuthbert gave the welcome news that the Bernhard Baron trustees who had “thought that the President's advisers were rather optimistic in their estimates of what they could achieve for the sum named,” had decided to increase their gift of £30,000 by a further grant of £5000 in order “that your plans should be carried to complete fulfilment without financial anxiety” Sir ARTHUR MACNALTY who, in the absence of the Minister of Health, responded for the guests, spoke of Hunter as the man who had introduced the exercise of the observant scientific mind into the study and practice of surgery He recalled that his predecessor Sir John Simon, the first chief medical officer of the central health department, was at the same time President of the College His training in scientific surgery led him from the study of disease in the individual to the prevention of disease in the community Living in more leisured times Simon worked for many years at Whitehall in the mornings while in the afternoons he operated or saw patients at St Thomas's Hospital The toast of the Hunterian Orator was proposed by Sir FARQUHAR BUZZARD with a warm tribute to Mr Fagge's re presentment of the great genius of John Hilton and a word about “the need to perpetuate in our profession the mind that was in Hunter”

On another page will be found some account of the special lecture given during the afternoon by Prof G E GASK, who related unpublished facts about John Hunter's work in the campaign in Portugal, 1762–63, and of his life in a base hospital at Lisbon

PUBLIC HEALTH

Four Years' Work at the Maudsley

Dr Edward Mapother's report on work at the Maudsley Hospital during the period from January, 1932, to December, 1935, is a record of steady achievement and development As an important teaching centre in psychological medicine, the hospital receives a large floating population of post graduate and under graduate students, to meet whose needs the plan of instruction has been modified by the formation of a teaching unit Dr Aubrey Lewis has been responsible for organising the unit, and has charge, with the help of three colleagues, of nearly half the beds, so as to include patients of both sexes and all types The remainder of the beds are grouped under firms, as at most general hospitals The hospital is now recognised as a school of the University of London, professorships in the university were recently conferred on Dr Mapother and Dr F L Golla, director of the Central Pathological Laboratory

Enlargement of buildings has not only made possible the accommodation of more patients but has greatly improved the teaching capacity of the hospital. In addition to the increasing number of post graduate students attending the D P M course held each spring, medical officers from the L C C mental hospitals are seconded to the Maudsley as clinical assistants for periods of six months at a time Indeed, the report suggests that those entering the council's mental hospital service are now “provided with a series of opportunities for obtaining psychiatric education and experience which is probably unequalled elsewhere” Undergraduate teaching is carried on in Pantia Ralli ward of King's College Hospital, which has been loaned for a period of years as an annexe to the Maudsley Hospital

In this report Dr Mapother discusses the advantages of forming a neuropsychiatric unit, intended chiefly for research and teaching Such a unit would have great value in the post graduate training of psychiatrists, especially if it were possible to tap the rich supply of material in the general hospitals of the Council Other developments suggested or foreshadowed in the report are that of building a hostel from which patients could go out to work even while attending the out-patient department—a solution for those whose chief need is removal from unhappy home conditions, and that, already approved, of providing accommodation for thirty children to be admitted under the children's department

Health Indices

Chadwick in England and Shattuck in the U S A based a novel campaign upon the proposition that the health of a community was dominated by environment, this being so, the health of a community should be capable of deduction from environmental data John Billings, the great American army surgeon, was attracted to this idea of estimating the healthfulness of places, but he did not pursue the matter In 1915 Dr Charles V Chapin, of Providence (R I), interested himself in comparing the health services of various local government units and introduced the “appraisal form,” which enabled the available health services of various units to be evaluated from a score sheet The objection to such a score sheet was that the marking is arbitrary, so the sheets of different assessors were not comparable, but they had some use in detecting improvement or the reverse in the total value of health services In a recent review[1] Dr K Stouman and Dr I S Falk, of New Haven (Conn), have developed further this method of evaluating the health of communities The “health indices” which they employ are made up of the appraisal form, “indices of vitality and health” (vital statistics), and “indices of environment,” which give meteorological and social factors A typical “short list” (which nevertheless contains 78 entries) is given from the city of New Haven, comparable with the statistical part of the annual report of a medical officer of health who puts in everything which might have a say in the health of the people

The object of these health indices is to obtain statistics, standardised for as many functions as possible, in order to obtain material for working out the causes of disease, or, in other words, to obtain facts for biometry The objection to them is that most of the information, though set down in mathematical form, has a specious accuracy which may be more misleading than rough guesswork Where the information is reliable, use can be made of it in a less complicated manner Hence, for practical purposes, “health indices” will not much attract health officers who have been trained in statistical epidemiology to the point of knowing its pitfalls It would be possible for any medical officer with a large expenditure of labour, and without any research, to fill up the full score sheet of 100 indices for his district, but he would gain little from it which he did not know before, and he would find that it was precisely in those matters where his entries must be provisional or uncertain that he wants accurate information On the other hand, given this full score sheet filled in by a reliable authority for Jericho, Timbuctoo, and Los Angeles, it would be possible to compare the health and services of the three towns, and indices so obtained might be valuable to the Health Organisation

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

BY A ROVER

III

It was not only on account of that lapse of memory which my colleague had noticed, that I knew I had had influenza Other things had happened which made it pretty certain that the fever of a fortnight ago was of this nature. On the side of the nervous system there was depression and of a somewhat elaborate kind, not a mere feeling that life was not worth living but a change in my whole philosophy of life which tended towards the positive not merely the negative aspects of pessimism I slept a great deal but dreamed vividly an almost new experience Brain work which was largely mechanical I could tolerate but an attempt at anything which required constructive thought was painful and doomed to failure

* * *

Then there was evidence that the heart was poisoned. The effort syndrome was definitely recognisable I chose the lift (when available) rather than the stairs even to reach the first floor—a practice I had hitherto scorned both as a time-saving device and for exercise I let the porters carry my bag I didn't mind it being thought that I was getting on in years so I invited people to help me on with my overcoat I walked more slowly than usual, even on the level. On one occasion I forgot and lifted the foot of a bed containing a pretty heavy woman whilst the nurse put blocks under the castors I had a heart ache for two days afterwards Two or three nights I woke with irregular action of the heart and, though my clinical sense told me the disturbance was of the nature of extrasystoles my depression whispered gloomily about fibrillation, the indication for an E C G and the propriety of suspending tobacco (which in any case gave much less satisfaction than usual) and coffee

* * *

And *again there was that tiresome cough* which seemed so meaningless since there was no catarrh and yet which was so greatly influenced by temperatures *effort, food and posture*

But the fever itself could scarcely have been anything else than influenza The epidemic was on the onset was abrupt, I had one horrible night during which my mind threshed through the hours trying vainly to link up paroxysms of a most painful tracheal bark with a dream-state from which I woke (as it seemed) dozens of times (How true despite the nurse's report is that asseveration of our patients that they haven't slept a wink all night) What other disease all said and done the duration of the acute stage of which may be only 48 hours can effect such a devastating change in the equilibrium of body and soul? We say that we have no criteria by which to judge what is influenza Rubbish! An infection which produces all this disturbance and yet may yield no physical signs *is* influenza And it is not the work of a mere coccus or bacillus either

* * *

The more we become familiar with diseases due to infection by filtrable viruses the more confirmed are we that the specific infection in influenza is of this nature Some of us held this view strongly even when B Pfeiffer had such powerful adherents Experience of psittacosis for example illumined the darkness considerably Here we saw a combination of a typhoid like state with a spreading form of pulmonary inflammation associated with bronchiolitis and œdema In the 1918–19 epidemic of influenza or rather amongst the more severe cases which occurred just before and just after the main wave of morbidity we saw the typhoid like cases both with and without, pulmonary symptoms and we also saw the pulmonary cases with their peculiar cyanosis extensive congestion of the lung and bloody sputum The memory of my first case of fulminant respiratory influenza (in 1918) remains vividly in my mind, especially the peculiar *cyanosis* The colour of the face reminded me of the only case of aniline poisoning I have ever seen—a medical student who *got a shock when he saw his face* in the mirror one morning He had been applying an aniline preparation to an inflamed ear But he *wasn't ill.* I *couldn't* place the young woman with the heliotrope face and the generalised bronchiolitis because I had neither seen such a case nor heard of it *How easy the diagnosis* is to-day!

* * *

Measles *is almost certainly another virus infection* Of all the common acute exanthemata it is the most likely to lead to serious nerve symptoms such as *encephalitis and myelitis*

I suppose it was some such inductive reasoning as this that led Sydenham to his conception of "epidemic constitutions"—that famous battleground between the bacteriologists and the epidemiologists Hippocrates it was who started the idea for he like Sydenham, loved to generalise from particulars For Sydenham it was the disease rather than the patient that possessed the constitution We are warned by some of those who are reluctant to let outworn notions die—when those notions were the product of the thought of great men—not to consider ideas that seem to us to be nonsense to-day to have been nonsense at the time they were uttered. The point is rather that these great men would, in the light of our present knowledge throw overboard their own notions much more quickly and entirely than do their reverent but slavish disciples. *Microbiology* gives the answer to the riddle that faced all the physicians however great their genius down to the time of Pasteur We are *told that there may* still be pearls to be had for the searching in the writings of Sydenham and those who followed him But the pearls are surely the *persistence of the man* and his painstaking work in the face of the fact that the key to his difficulties was hidden from him and could not be revealed until *new tools opened* up new methods of inquiry The same may be said of Hunter and of others whose genius came so near to finding the answer to the *riddle It is clear from careful* study of their writings, that they did not deceive themselves into believing that they had solved the essential problem *inherent in most diseases*—what *is* it that disturbs the equilibrium of the body and leads to that complex series of changes revealed in the study of the *sick man? Pasteur and Lister* and Koch following Leeuwenhoek gave the answer and the science of Infection was born

PARLIAMENTARY INTELLIGENCE

THE FACTORIES BILL

On Feb. 11th in the House of Commons Sir J. Simon, Home Secretary, moved the second reading of the Factories Bill. He said it was 30 years since any comprehensive measure for amending our factory code was last enacted by Parliament. While, of course, some useful and important amendments and extensions of our factory law had been made since that time, for example in 1907 and 1916, and a very important change in 1920, and again in 1929, still the main factory code remained the code of 1901. It was therefore high time that a new and improved code was passed, not only consolidating but amending and improving the existing law. Both the National Confederation of Employers' Organisations and the General Council of the Trade Union Congress had been consulted before this Bill was drafted and while therefore there would be a number of points in Committee on which there were sure to be differences of view, he was justified in anticipating that on much of the Bill there would be found to be a very large measure of agreement.

The questions of health were dealt with in the Bill in Parts I, III, and IV. These provisions involved in many respects a real advance. The first clause was important in that it made more precise the present law by including specific provisions in regard to the removal of accumulations of dirt and the cleaning of floors, which in many factories needed very careful attention. In Clause 2 they dealt with the important question of overcrowding and the standard of air space to be allowed. They wanted in principle to secure an increase in air space from 250 cubic feet to 400 cubic feet, which was the standard existing to-day in the best-appointed factories. The difficulty was to get the change rapidly made in the smaller works in certain industries. Adequate ventilation was as important as adequate air space. The proviso in Clause 2 was designed to secure, if possible, that existing works should comply with the new standard as soon as possible, but they were to be given time to do it. In the meantime they emphasised the importance of effective mechanical ventilation being provided, if a room was crowded. The existing factory code made no provision for ensuring proper lighting. The lighting clause in this Bill was an entirely new provision. Important new powers were also conferred under Clause 11. At present there was no power to require medical supervision in a particular works to meet a special emergency. For example, suppose there was an outbreak of anthrax during some process, or dermatitis, or sepsis, or conjunctivitis. There was no power now in the factory code by which the medical officers of the Department could say that there must be an investigation to find out how these outbreaks had occurred. In the same way, there was no power at present to meet cases where there was reason to apprehend that some substance was being employed that was likely to be injurious, the injury being caused through the material, or through one of the materials used. Again, there was no power at present to secure proper investigation with a view to stopping the injury in cases where young persons were being put on work which it was thought might prove too much for them.

It was high time to provide in the factory code that in cases of that sort it should be the right of the authorities to introduce, if necessary, medical supervision with a view to discovering what was the explanation, to stop the cause if they could, and to throw light on what might be a very obscure cause of trouble. Clause 11 would give the Secretary of State power to require reasonable arrangements to be made for the medical supervision of the workers, or any class of workers, either in a particular factory, or in any class or description of occupation. Part III of the Bill dealt with welfare provisions. There were certain welfare provisions already in operation. One might say that welfare work was an outcome of the war. It was intended to extend and make much more precise the welfare provisions contained in the Act of 1916. The existing provisions for the removal of dust were not adequate and they wanted to make them much stronger; that was done in Clause 46. New provisions for the control of underground workrooms in factories were included in Clause 51. Clause 54 was an entirely new and important provision; it was designed to protect people in the matter of lifting weights which were too heavy for them. Clause 48 dealt with the romantic operation called "shuttle-kissing"—that was to say threading the shuttle by mouth suction. That must be an objectionable practice and it was desirable to discourage it, although the information of the Factory Department of the Home Office did not go to show very definitely that any particular disease was thereby developed.

It was an extraordinary thing that the earliest Factory Acts made no provision about safety. It was largely due to the earlier factory inspectors going about their work that effective attention was called to the dreadful accidents due to unfenced machinery. It was in 1844 that provision was first made for promoting safety in factories and such provision had been steadily extended. This Bill took advantage of later experience and tightened up the whole code. In 1924 there were 312 accidents due to unfenced shafting, of which 44 were fatal; and in 1934 there were 164 accidents of which 21 were fatal. That illustration showed how much could be done if proper protective measures were taken. Accidents also occurred in connexion with tin rollers of ring spinning frames used in the cotton industry. In three years 1912–14 there were 52 such accidents; in 1913 the Home Office secured agreement about a definite standard of fencing for this machinery. The result was that this particular type of accident had been practically eliminated. In some years not one accident had been reported due to tin rollers. There were a great many other instances, such as accidents due to the failure of cranes, and accidents connected with electrical appliances, and he was satisfied that the tightening up of the regulations and rules on this subject would materially reduce accidents. The figures for accidents among juvenile workers showed a disturbing tendency to increase. In Clause 20 there were some important provisions which definitely prohibited young persons from cleaning what was called prime movers, which meant the sources of power, or transmission machinery in motion. Clause 15, which allowed access to unfenced machinery in certain circumstances, had the effect of prohibiting any person other than a male of over 18 from having anything to do with unfenced shafting. The Confederation of Employers had been induced to send out a circular to all the factories of the country calling attention to the disturbing feature of accidents to juveniles and embodying suggestions for reducing such accidents. The reports received by the Home Office showed that many firms were taking the action suggested, and it was important to watch the statistics to see how far these steps and the provisions in the new Bill resulted in the rate of juvenile accidents being reduced.

Taking the years 1924 and 1934, which were really comparable for this purpose, there was undoubtedly an improvement in the total number of accidents. In 1924 the total was 170,000, of which 956 were fatal. In 1934 when the numbers employed were about the same, the total was 136,800, of which 785 were fatal. If they took accidents connected with machinery, which was perhaps the most useful test, they found that they fell from 35,450 to 28,000, so that they could fairly say that the total accident rate had fallen in those ten years by about 20 per cent. In this Bill the Government proposed to introduce a tter system in regard to hours of work. They roposed to lay down for women and young persons at the maximum working week, the normal working eek, should be 48 hours They had to make some rovision for overtime but whereas under the isting law an employer could work a woman or oung person for a period of overtime every week ver and above the 48 hours—in the case of non textile ctories they could be worked for 12 hours overme every week, a total of 624 hours overtime in e year and in the case of a textile factory they ould be worked for the normal 48 hours and another hours in the week, or 300 hours overtime in the ear—it was now proposed to improve the law by miting the amount of overtime substantially As he Bill was drawn it provided that there might e as much as 100 hours of overtime, but they could nly be worked in a limited number of weeks he hought 30 in the year and there could not be more han 6 hours in any given week. At present it was ossible for women and young persons to work ntil 4 o clock on Saturday afternoons. Under this ill 1 o clock on Saturdays would be the closing ime as far as women and young persons were oncerned.

Summing up the measure Sir J Simon said that hat the Government were trying to do was to evise the industrial code which controlled the working ife of some 7 000 000 men women and young persons hey were engaged in framing what though it might ot be a perfect scheme would prove he thought n improved charter for their protection against ccident and undue fatigue and for promoting not nly industrial health and safety but greater ndustrial efficiency and prosperity The general dministration of the new law would be in the hands of an enlarged body of factory inspectors At present they had not enough inspectors

Mr. CLYNES said in many respects they could praise the provisions of the Bill but their praise must be balanced by criticism and by some blame He would describe the Bill as proposing to make a large number of small changes but avoiding the great issues and the big questions of factory reform There was a real demand for a substantial reduction of hours and the demand had been internationally expressed. Lately in the House of Commons there had been insistence on Parliamentary action to secure improved standards of physique and sums of money were to be provided to that end He (Mr Clynes) preferred that problems of improved health standards and physique should be handled at the source He would improve the conditions of employment, making them humane and lighter than much industrial work now was Conditions in our factories and workshops did not assist fine physical development He hoped in the Committee stage the Home Secretary would give a willing ear to appeals for the lowering of the hours of work. In the view of the Labour Party overtime ought to be more severely limited or abolished The provisions in regard to overtime in the Bill were on the whole too generous to the employers and unjust to a large number especially of women workers The Labour Party on the Committee stage would strongly resist overtime for young persons and women. He was a little disappointed that Sir J Simon had failed to give any definite indication of the extent to which the number of factory inspectors was to be increased for the whole value of this measure would depend on the watchfulness and supervision and activities of the factory inspectorate A serious omission from the Bill was that no proper rest in the year was secured for the average worker by means of holidays The Labour Opposition approved the general purpose of the Bill and accepted it as being in principle something that had been too long delayed

Viscountess ASTOR said that in many ways this was a splendid Bill but it was their duty to help the Government to make it an even better one Sixteen per cent of the children who entered our elementary schools were physically defective and they were going to be allowed to go into factories at 16 and to work a 48 hour week with overtime She did not think that they would get the blessings of the factory inspectors for juveniles who worked nine hours a day under modern conditions. Many people objected to women in industry being classed with children; it was perfectly absurd If women were of a certain age and strength and wanted to work overtime in the same way as men she did not see why they should not do so, but she objected to young persons up to 18 being worked overtime These children got tired and then accidents happened She hoped that the Government would agree in Committee to limit the hours to 40 per week. The amount of gross overwork imposed on young persons was incredible in these days If we were to stop the falling birth-rate and be an A1 nation we must protect our young peoples The time was ripe for raising the age for the entry of children into factories to 15

Mr MANDER said the Liberal Party would support the second reading of the Bill The measure however was by no means heroic it needed strengthening while showing a substantial advance in many directions the Bill indicated a retreat in certain directions It was deplorable after the Washington Convention that the Government had not taken this opportunity of amending the law in regard to the hours of work for men The question of working hours was a health question; long hours of work affected men just as they affected women He hoped that they would be able to improve the Bill in Committee

After further debate,

Mr SHORT said that since 1918 we had just tinkered with this problem. We were lagging considerably behind other countries so far as many labour laws were concerned This Bill was stamped on almost every page with the word compromise —compromise with the employers, but not with the workers; compromise with vested interests but not with humanity He could not regard the Bill as a great reform It was not a great charter but a disappointing measure But though he was critical of what he considered to be the failing of the Government in this Bill to deal with the bigger issues, that did not mean that the Labour Opposition would not coöperate actively to ensure that the measure was improved in Committee

Mr WEDDERBURN Under-Secretary of State for Scotland said that the Government were grateful for the generally favourable reception which had been given to the Bill As to the question of the 40 hours week, it had never been the purpose of factory legislation in this country to go beyond the limits of what was considered necessary to ensure the safety and the health of the workers in the factories Factory legislation here had never dealt with measures which could only be justified on general social and economic grounds as for example, the extension of leisure beyond that minimum which was necessary for health and safety A Minimum Hours Bill would be part of the policy of the Minister of Labour and would not be relevant to the functions of the Home Office He hoped that the House would not think that the Government anticipated that the maximum hours of overtime permitted by the Bill were likely to be normal The Bill did a great deal to restrict the overtime which was allowed by our present law The question of annual holidays with pay was inevitably connected with rates of pay and remuneration and it would therefore be outside the scope of the Factory Acts The Government quite appreciated and shared the general desire that working conditions generally should be in advance of the minimum requirements laid down in this Bill but it was not the function of legislation to prescribe compulsorily what was regarded as the optimum standard It was the purpose of legislation to ensure that the conditions which were decided on and which were approved by public opinion and settled by the great majority of workers and employers should not be vitiated or taken advantage of by a minority who did not choose to recognise these generally accepted standards and attempted to derive advantage for themselves by refusing to observe them.

THE MINISTER OF HEALTH

The debate was resumed on Feb. 15th when Sir **KINGSLEY WOOD** commended the Bill to the House because he said many of its provisions embodied that advance in national health policy which was rightly occupying so much attention to-day. Whilst it was right to continue efforts to cure illness and physical defects, more should be done to prevent them. Many people looked forward to the time when doctors would be paid when people were well, and fined when they were ill. There was no doubt that incapacitating sickness and accidents in industry were still heavy, and much of it was avoidable. "Public Enemy No. 1" was colds and influenza, which accounted for about 25 per cent. of absences from work. The medical profession had not yet found an instant remedy for these. Some of the best safeguards against disease and illness, especially of a minor sort, were, in addition to shorter hours and longer holidays good housing, airy schools good food, clean streets, and open spaces. But the efforts could not stop short outside the factory door, and much could be done in promoting the health of the working population by more medical supervision and more welfare provisions.

The need of further statutory provision for the lighting of factories was clearly established, for conditions in many places were far from satisfactory. Clause 5 of the Bill provided that there should be suitable and proper lighting in every factory and for every part of the factory. The Home Secretary would have power to define by order what was adequate and suitable illumination for factories or processes, and certain minimum standards would be laid down.

Under Clause 11 there was an important development towards assisting preventive medicine. Under the existing Act there was power to require medical examinations as a permanent arrangement in codes of regulations for dangerous trades; but it would be of great value to employers and workers that arrangements for medical supervision could be made from time to time in particular works and in certain circumstances. He had in mind cases where there might be an outbreak of dermatitis where irritating substances were being used, or where there had been an introduction of new chemicals likely to be injurious to the workers, or where an outbreak of anthrax was suspected. In such cases the Home Secretary could make special regulations requiring reasonable arrangements to be made for medical supervision of the health of the people so employed. This would be a useful provision for protecting the health of the workers and for reducing short time. The Home Secretary would also be able to make special arrangements requiring reasonable medical supervision of young persons who might be employed on work that might cause risk of injury to their health. Some of the welfare provisions in Clause 8 should also have an important bearing on the general health of the workers. There was to be suitable accommodation for workers' clothing, with arrangements for drying wet clothes. He also attached importance to the facilities laid down for the seating of women, in preventing excessive fatigue and ill-health. Clause 46 made an important modification of the law with regard to the prevention of injurious affections of the lungs. The new provisions required workers to be protected not only against the breathing of dust or fumes of an injurious or offensive character, as under the present law, but also against the breathing of any kind of dust to a substantial extent.

The suggestion that the Bill should prohibit the employment of women in factories during the last six or eight weeks of pregnancy raised a matter of great difficulty and complexity. The British Medical Association had put forward certain views on the matter but the Association's memorandum said there seemed no valid reason why a pregnant woman should not perform some work of a suitable nature up to the last week or two of pregnancy, and that it would be a hardship if cessation of factory work were to be made compulsory. One of the difficulties was that if it were to be made a penal offence for a woman to be employed in a factory for a stated period before confinement, it would be quite impracticable to penalise the employer and the penalty would have to be imposed on the woman herself. Then there arose the question of who was to determine the period of pregnancy. A good many women would resent a compulsory prohibition of the kind suggested, and it must be asked whether such a prohibition might not have a bad effect by discouraging a woman from availing herself of antenatal services at an early stage of pregnancy.

The Bill also proposed, by amendment of the law and by administrative action, to improve the medical arrangements for the examination of young persons by the certifying surgeon. The certifying surgeon would in future be required to give a positive certificate that the young person was fit for employment, and not merely the negative certificate that he was not unfit. Steps were also being taken to ensure a greater measure of coördination of the various State health services. The Bill made the important provision that Education Authorities should supply the school medical history to the certifying surgeon. By that means, the surgeon would have before him the whole medical history of the person being examined. On behalf of the local authorities he (Sir Kingsley Wood) could say that they were anxious to coöperate in the efficient enforcement of the provisions entrusted to them by the Bill. The Bill would mean a great betterment in the health and conditions of many millions of industrial workers.

MEDICAL VIEWS

Sir F. **FREMANTLE** said that from his considerable experience of inspecting factories in this country they were usually speaking temples of health. It seemed to him that they were on the line of general steady progress in this matter. He hoped that the Government's proposals for physical recreation would be a complement to the provisions for increased leisure, though he did not believe that long hours were necessarily detrimental to health. Monotony, too, had been found in certain circumstances to be preferred by the workers, because it involved less mental concentration. Sir Kingsley Wood had referred to the control of ventilation and temperature in factories, but he had forgotten two other essentials to comfort—the humidity and the movement of the air. The katathermometer, which showed the effect of these, was not yet generally used in the factory system. An advance had been made in the appointment by the Home Office of certifying factory surgeons responsible to them and not to the educational or sanitary authorities. For these the title examining surgeon was very suitable. A medical officer was needed whose job it was to study the health conditions all the way through the factory and to make suggestions about the worker, the conditions of the factory, or the processes as far as they affected health. The difficulty in employing local medical officers on the grounds that secret processes had to be guarded from competitors ought to be overcome. Properly appointed officials would never be guilty of revealing secrets of any kind. There ought to be a much closer connexion between the factory medical officers of the Home Office and the local medical officers of the health and educational authorities than was aspired to in this Bill. Under the Bill a dossier from the schools was to be passed on to the examining surgeon who would examine the children going into industry and that was a good provision. Though he had suggested that the medical officer who had been examining the child during the whole of his or her school life was the best qualified to decide whether the child was fitted for factory life He regarded this Bill as only a temporary measure while they were thinking out a way of improving the general liaison of the health services Industrial medicine had become vitally important to industry and to the health of the nation and must be under specially trained medical officers Hitherto industrial medicine had been entirely left out of the general education of the medical man but there was growing up a generation which was studying this question He was afraid however that the ordinary medical men in the country were not being properly trained for what he believed would be the duties which would be cast upon them in the future

Sir ERNEST GRAHAM LITTLE urged that a larger measure of medical supervision should be provided under the Bill He did not think that there was any medical reason why they should differentiate between men and women in the Bill he would like the division simply to be between adults and adolescents the latter of course requiring some age qualification Special measures might be called for on account of age but not he submitted of sex with one exception that of pregnancy Pregnancy ought to be regarded as in the nature of an illness and treated according to the individual case They ought to legislate with some attention to basic facts He would plead for much better medical service in factories. The chief inspector of factories made a very impressive statement in 1932 when he said that they had come to the limit of usefulness in devising gadgets to prevent accidents and more consideration should be given to the personal factor That was borne out by statistics One could predict that a certain group of persons would have accidents It was the same in cases of idiosyncrasy Out of the total number of disabilities which caused absence from work in factories practically one-half were due to external irritants and disease of the skin By far the most important industrial accident or disease was cancer which was on the increase all the time and it was not notifiable. In the last three years there were 535 cases and 123 deaths The cases of cancer referred to in these reports arose from two causes—oil and tar Oil of course was the lubricant used in the cotton industry and it was the cause of an extraordinary large mortality In the last report of the Registrar-General the figure for the mortality from cancer produced by oil was 4 per 1 000 000 of the ordinary population but among cotton spinners it was 131 per 1 000 000 It had been ascertained that the production of the disease by oil depended upon the nature of the oil —the heavier the oil the more cancer it produced and experiments which had been tried in Manchester chiefly showed that these oils could be identified and that it was possible to determine beforehand what would happen if a certain oil was used A formula was now available which could be very easily applied and by which it was possible to determine before a particular oil was used what was likely to result from its use in the matter of cancer production and the injury to the skin caused thereby Although that information had been quoted in the medical press for the last three or four years he saw no mention of it in any of the factory inspectors reports This information had been passed on to the body which dealt chiefly with petroleum manufacture The incidence of cancer caused by tar was 1 per 1,000 000 of the general population but in the case of tar workers it was 665 per 1 000 000 and in the case of chimney-sweeps who were subject to somewhat similar conditions it was 531 per 1 000 000 The opportunity afforded by this Bill to increase the amount of medical supervision should not be lost Medical supervision should be provided for all workers irrespective of age or sex

UNDER SECRETARY S REPLY

After further debate Mr GEOFFREY LLOYD Under-Secretary Home Office replying to the debate said that the provisions in the Bill in regard to medical supervision gave an important new power It enabled the Home Secretary in several circumstances to see that there was undertaken proper medical supervision on certain processes He (Mr Lloyd) would give the House an illustration as to how useful such a power would be Fortunately they had one or two examples where medical supervision had taken place not compulsorily but voluntarily A few years ago there were developments in some of the factories making accumulators for motor-cars which led to an increase in lead poisoning They had a considerable number of cases—over 100 in one year—and being progressive they approached the Home Office which arranged that there should be medical supervision in these works. A young doctor was put in charge of the work and he went into it very scientifically Immediately there was the slightest indication of lead in the body the man was either taken off the work in which lead was used or a radical alteration was made in the processes from the point of view of the elimination of lead Owing to the measures that were taken the cases of lead poisoning dropped rapidly and during the last three or four years there had been in one factory only one or two cases at most and in the others none

The Bill was read a second time without a division

The financial resolution in connexion with the Bill was agreed to in Committee

THE TREND OF POPULATION

A Dangerous Decline

In the House of Commons on Feb 10th Mr CARTLAND moved —

> That this House is of opinion that the *tendency of the* population to decline may well constitute a danger to the maintenance of the British Empire and to the economic well being of the nation and requests His Majesty s Government to institute an inquiry into and report upon the problem and its social and economic consequences and to make recommendations in regard thereto

He said that this problem was not merely political and social but it also affected medicine psychology economics and morals From expert estimates of the future population it would be possible to draw a picture of this country in a hundred years time with derelict villages silent factories empty schools and with only perhaps the hospitals and almshouses filled

This problem was not only one of the future it had risen to-day and three facts were incontrovertible The birth rate had been falling steadily and consistently since 1875; and within three years the number of births for the first time would no longer exceed the deaths Secondly even if every child born to-day were to live to maturity the birth rate would still not be high enough to maintain the population at the present level; there were not sufficient females being born to replace the mothers Thirdly a serious alteration had taken place in the age of the nation the youth dwindling and the aged increasing in proportion. Would the programme and policy that the country was putting into operation to-day relieve or aggravate these circumstances? The spread of birth-control methods was not the sole explanation of the decline because it did *not* answer the question why those methods were being used The whole tendency of modern life was towards small families and too often the standard of life had become a standard of luxury but he did not believe that even that was absolutely incompatible with an increased family While national economic circumstances had *affected* to some extent the fluctuations of the birth rate they had never affected its trend. Another serious matter was the growing number of females and juveniles employed in modern industry What was going to happen when the stream of these became a mere trickle? The death rate had been pretty steady since *1910* and could hardly be lowered appreciably and even through the maternity services the trend would not be reversed

That had been going in the same direction since 1875. The nation was on the edge of an abyss. There was still time to climb back, but the situation was very dangerous.

Mr **SANDYS** seconded the motion. He said that the problem of declining population was not confined to this country, but concerned Europe, the United States and the British Dominions. In China and India the population was slowly increasing and it was estimated that in Russia it would be doubled to some 320,000,000 before there was any likelihood of a decline. It was true that the population in this country was still growing because of the remarkable decline in the death rate, which had fallen from 22 in 1871 to 11 in 1935, though the birth-rate had halved itself in that time. Very little difference had been made, however, in the expectation of life of adults, for in a man of 65 it had increased since 1871 only by some nine months. The change had been in the extremely satisfactory decline in infant mortality, the deaths in the first year having fallen from one in seven live births in 1886 to one in twenty in 1935, but further improvement was still necessary. The decline in our population, however, could never be arrested merely by continued reduction in infant mortality. He went on to quote forecasts of the future population showing how, if present tendencies were maintained, in sixty years' time 64 per cent. of the women in this country would be beyond the child-bearing age, and how the population of England and Wales would in a hundred years have dwindled to a mere 4,500,000. By 1976 children under fifteen would have changed from 10,000,000 to 4,000,000, people over 65 from 3,000,000 to 6,000,000, and the age-group 15–45—with the bulk of the nation's workers—from 21,000,000 to 12,000,000. As a remedy there were two alternatives open—to forbid birth control by making it illegal, which he thought would be a retrograde step, or so to alter social and economic conditions as to make people want to have large families, a course which would commend itself to all. They were asking for an inquiry to be held and action taken at the very earliest possible moment. If the present tendency was allowed to continue unchecked action that to day would suffice to remedy the entire situation would in ten years be totally inadequate.

Mr **PARKER** said that a marriage bounty policy was not likely to cure the population problem in this country. The first thing was to convince people that to maintain the race was of itself desirable. Secondly, it had to be made worth their while to do so by providing better maternity services and proper nutrition, care, and education of children, and a certainty of a job when they grew up. And thirdly, and most important, the danger of war had to be eliminated.

Mr R. **ACLAND** believed that it would be wholly improper to oppose birth control. Other nations had tried that wholly without effect. He urged that birth control clinics, or rather children's clinics, should be encouraged, for otherwise unhealthy methods might be exploited. The first work of the committee of inquiry, which he hoped the Government would appoint, ought to be to investigate the different causes of childlessness. He thought the fear of pain and maternal mortality were important factors as well as the whole economic and political environment.

Sir **FRANCIS FREMANTLE** said that long before contraceptive methods were introduced the decline had begun. It was not merely one in quantity but in quality, for as he looked back on the large families he had known it was not the eldest but the younger sons who had taken the highest places in their careers. Therefore, by a continued decline in the birth rate an immense amount of quality and ability would be lost. This country was thus losing the power to compete with other countries. He asked the House to remember the great labours in 1913 of the National Birth Rate Commission, under Bishop Boyd Carpenter and its valuable reports in 1916 and 1918. He thought that the time was ripe for a further overhauling inquiry, and although they could not expect a very great deal from it.

After further debate, Mr **HUDSON**, Parliamentary Secretary to the Ministry of Health, said that the Government proposed to accept the motion before the House and to make or, rather, to continue their investigation. Some hon. Members in the debate had painted appalling pictures of the steadily declining birth-rate. The interesting fact was that since 1933 for the first time in history it had remained stable in this country for four years in succession. Mr Cartland quite rightly saw that contraceptive methods were the means and not the cause of the decline—an important distinction. It was very difficult to reach any considered opinion on this problem with the information at present at their disposal. A very large preponderance of persons in the prime of life at present was due to an excess of births at one time which must inevitably be followed by an excess of an older age group. The juvenile population to-day sprang from years with a low birth-rate and the number of old people was the result of an earlier time—and this was the reason for this enormous bulge in the centre age-groups. He thought the estimates of the future that were being made to-day by certain statisticians were possibly as wide of the mark as those that were made a hundred years ago, with the knowledge they then had of the trend of population. The Government welcomed this debate, and proposed to intensify the inquiry which was continuously taking place. It was clear that this intense investigation might lead to interesting conclusions. They hoped to obtain sufficient information to indicate what their policy should be.

The motion was agreed to.

INSANITY AND DIVORCE: NEW SCOTTISH BILL

In the House of Lords, on Feb. 11th, Lord **ALNESS** moved the Second Reading of the Divorce (Scotland) Bill, which extends the grounds on which decrees for divorce may be granted in Scotland. He said that the first ground for divorce in the Bill was that of desertion and the second insanity. The period provided by the Bill during which the insanity must subsist was three years. The majority report of the Royal Commission held that insanity (1) defeated the purpose of the marriage relationship, (2) made marriage as a contract impossible of fulfilment, (3) lay outside the reasonable contemplation of the parties at the date of the marriage, and (4) differing from all other bodily disorders involved the removal of the insane person and so brought to an end every phase of marriage. Some of the most tragic cases in social life had occurred in consequence of this supervening malady. The first of two objections that had been taken to insanity as a ground for divorce was that the afflicted person might recover. The evidence before the Royal Commission established that after five years the cases of recovery were only 1 per cent., and after three years a very slightly higher rate. Moreover, in these rare cases of insanity it was surely, eugenically and otherwise, undesirable that the parties should resume cohabitation and should breed. Insanity might recur at any moment. Again, it was objected that lunacy was a misfortune, not a fault. That was true, but, divorce decrees were not given as punishments. There were in Scotland 20,000 insane persons confined in asylums. The Board of Control had not been able to provide him with the precise figures of those who were married, but it could not be disputed that there were at any rate thousands. The evil was therefore widespread. It was important to recall that divorce on the ground of insanity was the law in New Zealand, Scandinavia, Czecho-Slovakia, and Portugal. The late Lord Birkenhead had stigmatised the present system as savage in conception and devastating in its consequences. The change proposed in the Bill was one that was in obedience to the profoundest considerations of social policy

Other grounds for divorce under the Bill were cruelty penal servitude after a sentence to that effect or a commuted death sentence conviction three times of a crime since the marriage and within 5 years of the raising of an action of divorce and sentence of imprisonment for not less than 6 months the crime involving either dishonesty or personal violence; and habitual drunkenness

Lord **MacMillan** in supporting the Bill said that although lunacy had not hitherto been a ground for divorce in Scotland it had commended itself to the Royal Commission

Lord **Strathcona** said at that stage he could not express either approval or disapproval of the principles of the Bill It must rest with their Lordships to decide according to their convictions.

The Bill was read a second time

Cruel Films

In the House of Commons on Feb 11th Sir **Robert Gower** presented the Cinematograph Films (Animals) Bill, a measure to prohibit the production or exhibition of films depicting suffering to animals or in the production of which suffering may have been caused to animals. The Bill was read a first time

QUESTION TIME

THURSDAY FEB 11TH

Unemployed Men at Papworth Settlement

Mr **Rowson** asked the Minister of Labour if he was aware that young men from the distressed areas and from Government training centres who were not suffering from tuberculosis themselves were being employed in Papworth workshops Cambridgeshire and were working side by side with persons suffering from tuberculosis and if he would consider the advisability of discontinuing this practice —Mr **Ernest Brown** replied Yes Sir I understand that 24 men who were trained at Government training centres, as well as a considerably larger number of other non tuberculous men are at present employed at the Papworth Village Centre These men were informed before they took up employment at Papworth that they would be working in a settlement for tuberculous persons and recruitment is on a voluntary basis. My right hon. friend the Minister of Health will deal more fully with the medical aspect of the matter in reply to a later question but I understand that there is no special risk of infection, and in these circumstances I do not feel justified in refraining from giving suitable men from the training centres the opportunity of taking up employment at Papworth if they so wish

Mr **Rowson** Is the right hon gentleman aware that the men claim that they have been deceived into going to Papworth and would like to get away as early as possible and they have been told that they will not be discharged and that they dare not leave on their own ?—Mr **Brown**: I am not aware of that The work that is going on at Papworth is a valuable and wonderful experiment

Mr **Tinker**: Might not the fact that they work in these surroundings make them feel that it has some influence on their health ?—Mr **Brown**: That question does not arise

Mr **Shinwell**: Cannot the Government devise more suitable schemes for training men than those in which the men run some risk of infection ?—Mr **Brown** I have answered the question on the Paper —Mr **Shinwell** Would the right hon gentleman answer the questions a little more clearly ?

Sir **Francis Fremantle**: Is it not a fact that every precaution, practically speaking is taken at Papworth, and that there is practically no risk in these people working side by side with one another

Mr **Rowson** then asked the Minister of Health if he was aware that young men from the distressed areas and from Government training centres who were not suffering from tuberculosis were being employed in Papworth workshops, Cambridgeshire and were working side by side with persons suffering from tuberculosis and if he had obtained the opinion of his medical experts as to whether or not this practice from a health point of view was desirable and should be allowed to continue —Sir **Kingsley Wood** replied Yes, Sir These young men work in hygienic workshops and also in the open air They are aware before they come that they will be employed in a tuberculosis village settlement They do not reside there The tuberculous patients are under constant medical supervision and are trained in the necessary precautions to guard against conveyance of infection Under these circumstances, I am advised that no special risk is involved

Mr **Rowson** Is not the sole purpose of setting up tuberculosis sanatoria the prevention of infection and contagion, and if that is the case what is the use of sending tuberculous cases there and putting non T B men side by side with them on the same bench ?—Sir K. **Wood** I do not think there can be any objection These men go quite voluntarily and as far as any risk is concerned they are just in the same position as the medical staff and the nurses and other people associated with them

Mr **Rowson**: If this is not regarded as a tuberculosis colony now is it regarded as an ordinary commercial institution competing with other businesses of a similar character on the basis of cheap labour ?—Sir K **Wood**: No, Sir My opinion, as the hon Member has asked for it is that this is an excellent institution doing a fine piece of work.

Mr **Mabane** Are not these questions calculated to damage the sale of admirable goods manufactured at Papworth workshops which are in a perfectly hygienic condition and are rendering a great service to disabled men ?

Alleged Press Persecution

Sir **Assheton Pownall** asked the Home Secretary whether he had now heard from the Newspaper Proprietors Association and the Newspaper Society in answer to his recent communication to them with regard to recent complaints against certain press representatives —Mr **Lloyd** replied: My right hon. friend has received communications on this subject from the Newspaper Society the Press Association Limited and Reuters forwarding resolutions passed by these bodies The Newspaper Proprietors Association informed my right hon. friend in a letter dated Feb 4th that the Association have decided to appoint a committee to investigate and recommend any steps which may be necessary to secure the end in view "

Replying to Lieut-Commander **Fletcher** who asked if the Home Secretary was contemplating any action in the matter Mr **Lloyd** said no doubt his right hon. friend would wish to consider the replies he had received from the associations concerned

Protection of the Public against Air Raids

Sir **Nicholas Grattan Doyle** asked the Home Secretary what steps he proposed to take for the protection of the public in those areas in which the local authority had refused or failed to take precautionary action against the effect of air-raids —Mr **Lloyd** replied These areas will share in the benefit of general precautionary measures taken by the Government but this will not compensate for the future of any district which is liable to attack to take effective measures on its own account and I trust that all local authorities will see their way to coöperate with the Government in this matter I am glad to take this opportunity to say that the number of local authorities who are not coöperating is now seven and not eight as indicated in my reply on Jan. 28th as the Borough of Ilkeston is prepared to assist in the preparation of protective schemes

Bogus Charities

Sir **Nicholas Grattan Doyle** asked the Home Secre[illegible] whether his attention had been called to the great [illegible] bogus charities and house-to-house collections [illegible] whether with a view to removing these frauds [illegible] public, he would introduce legislation for the com[illegible] registration of collecting charities, as had been [illegible] the case of war charities and of charities for the [illegible] Mr **Lloyd** replied: My right hon friend has [illegible] complaints from time to time of the activities of [illegible] charities especially of some which make house-to-[illegible] collections The compulsory registration of collecting charities was carefully considered by a Departmental Committee which reported in 1927, but the Committee decided not to recommend the institution of such a system Legislation introduced in 1929 to implement recommendations of this Committee for an alternative measure of control failed to pass into law, and my right hon friend cannot hold out any hope of fresh Government legislation on the subject

Extensions to Southmead Hospital, Bristol

Mr KELLY asked the Minister of Health what was the area of the land recently purchased for £11,500 from the Bishops Monk Horsfield estate trustees by the Bristol Corporation for extensions to Southmead Hospital, what number of patients the extension to the hospital was likely to accommodate, and whether the land in question was formerly agricultural and therefore exempt from local taxation —Sir KINGSLEY WOOD replied I am informed that the area of the land at Southmead Hospital which the Bristol Corporation have agreed to purchase, subject to my consent to the necessary loan, is about 24 acres and that the extensions at present proposed by the Corporation include the provision of 100 beds for patients The answer to the last part of the question is in the affirmative

Experiment with Sub-Standard Recruits

Mr DAVIDSON asked the Secretary of State for War the total weekly cost, per head, involved in the recent experiment to bring recruits, previously declared unfit, up to military physical standards —Sir V WARRENDER, Financial Secretary to the War Office, replied The extra cost over and above that of a normal recruit was 3*s* 2½*d* a week for each man This does not take into account the overhead expenses which, although not appreciable in respect of the small numbers involved, would be considerable if the experiment were applied on a large scale

List of Approved Societies

Sir ARNOLD WILSON asked the Minister of Health whether he was aware that the last-published list of approved societies related to the year 1930, and whether he would consider issuing it annually in future as a Parliamentary paper available to members free on application and not, as at present, on payment —Sir KINGSLEY WOOD replied A new list of approved societies is already in course of preparation It has not been found necessary to issue this list at intervals of less than five years as the changes from year to year are relatively unimportant

TUESDAY, FEB 16TH

Public Health Law in Scotland

Mr WESTWOOD asked the Secretary of State for Scotland if he was aware of the desire amongst local authorities in Scotland for the consolidation of Local Government Statute Law relating to public health, and what action he proposed to give effect to the desires of the local authorities —Mr ELLIOT replied I am aware that Scottish local authorities have expressed the desire for the consolidation of the law relating to public health I have every sympathy with their views and I am keeping the matter before me in my consideration of the report of the Committee on Scottish Health Services

Vagrants and 'Red Biddy" Drinking in Scotland

Mr WESTWOOD asked the Secretary of State for Scotland if he had had time to study the report of the departmental committee on vagrancy in Scotland particularly Chapter III, paragraph 28, which dealt with the methylated spirit and Red Biddy drinkers and the addicts to even worse concoctions, if he had considered the recommendations contained in Chapter XII paragraph 152 for dealing with these addicts, and if so, what action if any, was proposed to give effect to the recommendations —Mr ELLIOT replied The report is under consideration As stated in the report, the drinking of methylated spirits Red Biddy and other such concoctions is not confined to vagrants The recommendation in paragraph 152 that vagrants addicted to such practices should be compulsorily detained raises a very wide question which requires careful consideration.

A NEW FORM OF U-V LIGHT METER

Mr J R Ashworth, D Sc, of Rochdale, has devised an instrument for measuring the ultra violet rays of the atmosphere, using a wedge of wire gauze The instrument is contained in a metal box 6¾ × 3½ × 1½ in, in the lid of which is a sheet of glass opaque to visible rays but permitting rays between 3000 and 4000 Angstrom units to pass Beneath the glass is the wedge, lying in a tray which has 12 holes corresponding to 12 steps of the wedge, the tray covers a piece of sensitive photographic paper The thick end of the wedge is nearly opaque to the rays whilst they print themselves strongly at the thin end, the intensity of the rays being measured by the number of printed spots to be seen on the paper The proper qualities for a wedge are these it must be transparent to U-V rays and of a material able to withstand for an indefinite time exposure to strong light, variations of temperature, moisture, and other external influences, it must be reasonably accurate step by step, and it must be capable of being reproduced exactly and with facility These conditions are fulfilled by using wire gauze The wedge is built up by placing over the first layer of wire gauze another layer one step shorter, over this again another one step shorter than the last, and so on. It follows from the mode in which the wedge is constructed that if the fraction of the rays which passes one layer is f, then that which passes the second superposed layer is f^2, and that through the nth layer is f^n, hence the logarithm of the intensity is proportional to the number of spots observed on the sensitive paper, and the ratio of one step to the next is the same at any part of the scale The increase of intensity which each step represents is such that about 20 steps include the extremes likely to be met with An instrument made on these lines may be had from Messrs Negretti and Zambra A table of intensities corresponding to any given number of spots is supplied with the instrument and no calculations have to be made when the instrument is in use The spots are read in a good light as soon as the paper is taken out of the meter and no chemical treatment or washing is required. If the intensity of the ultraviolet rays is very great the twelve steps of the wedge may be insufficient for its registration, but by superposing on the wedge extra layers of wire gauze, of the same mesh as in the wedge, the range of the meter may be extended to any suitable degree The instrument is designed to receive rays from the sky covering an angle of 45° around the zenith when the surface of the glass is in a horizontal plane Daily observations are recommended, but the effects on the sensitive paper are cumulative and several days' exposure will give a reading equivalent to the sum of the separate days Photographic paper of appropriate sensitivity is supplied with the meter and can always be repeated of the same standard The instrument is strongly constructed and will stand prolonged exposure to hot or cold or wet weather without deterioration The Department of Scientific and Industrial Research has reported favourably upon it and the instrument is now in use at Southport, Salford, Rochdale, and other places

---

GLASGOW ROYAL INFIRMARY —The cost of building the new nurses' home at this hospital is, it is stated, to be met by a contribution from the Lipton Trust and will form a memorial to Sir Thomas Lipton The home is to be built in Cathedral square and is expected to cost over £100,000 The chairman pointed out that if the recommendations of the Scottish Health Services Committee were adopted they would carry the voluntary hospitals into close coöperation with the local authorities "We would welcome coöperation but as business men and good citizens we dread the waste caused by competition in this important field of public service" The ordinary expenditure of the Royal Infirmary last year was £118,424, which excluded capital expenditure

OBITUARY

THEODORE HARTMANN JUST M.B Camb F R C S Eng

Theodore Just who died on Feb 13th after a prolonged and distressing illness will be widely missed and St Bartholomew's men past and present have special cause to mourn the loss of a friend whose virile enthusiasm in work and play made him a prominent figure in hospital life Born in 1886 he was the only son of Sir Hartmann Just K C.M G C.B of the Colonial Office He was educated at St Paul's where he gained both academic and athletic distinction He was capitation scholar foundationer Smee prizeman and John Watson prizeman. He was in the Rugby football fifteen for three years being captain in 1904; he rowed in the school four and he won the athletic challenge cup in 1904 and 1905 It was during his time at St Paul's that Just first became known to his friends as Father an affectionate nick name which has stuck to him throughout his career

[Photograph by Hay Wrightson

MR. JUST

From school he went to Trinity College Cambridge, with an exhibition and took a first in the natural sciences tripos thence to St. Bartholomew's Hospital, where even in his early days as dresser to Sir Anthony Bowlby he was marked *as a man of outstanding ability* as well as keenness. He qualified M.B B Chir in 1912 became Sir Anthony's house surgeon and as such displayed the enthusiastic and untiring devotion that was to distinguish his subsequent professional activities Then as later it was common for him to spend the whole night by the bedside of an ill patient watching for the moment when surgical intervention might be essential A further period as house surgeon this time to the throat nose and ear department brought him under the influence of Mr Douglas Harmer who stimulated in him a lasting interest in this branch of surgery Before he specialised however he gained more general experience as demonstrator of pathology still at St Bartholomew's and was holding this post and also working in the throat department at the outbreak of the war Just joined up immediately and was in France by the end of August 1914 serving as bacteriologist and then as surgeon specialist After the war he returned to his work in the pathological department and in 1920 took his F R C S Shortly after this he was appointed assistant surgeon to the Throat Hospital Golden square and in 1922 soon after his marriage to Alice Marie daughter of H B Mactaggart was made aural surgeon to St Bartholomew's He also held appointments as aural surgeon to the National Hospital Queen square to the Alexandra Hospital for Children Swanley and to the Lord Mayor Treloar Hospital at Alton the Foundling Hospital the Harrow Hospital and the West Suffolk Hospital. His surgical work was thorough careful and well judged and he never spared himself the effort of providing opportunities for the cheerful talk which brings encouragement to the patient awaiting operation or recovering therefrom It was this sympathetic quality joined to ability that brought him success in practice

To Theodore Just's prowess at school in athletics and games we have already referred At the *university he soon made his name as an exceptional* half miler He represented Cambridge against Oxford in 1907 as second string when he ran third and was awarded his half blue In 1908 he reached his peak as an athlete; he got his full blue and won the Inter *Varsity half mile in 1 min. 55 8 sec.—a time that has* only twice been beaten In the same year he won the A.A.A half mile championship and represented Great Britain in the Olympic Games in the half mile and in the 1600 metres relay race He was elected president of the C U A C *for the 1909 Inter* Varsity sports and was beaten by inches by Stormonth Darling At St Bartholomew's he was the main stay of a team that won the Inter Hospital Athletic Shield and also played three-quarter in the Rugby fifteen In later years he became a keen golfer and was a well known and popular figure at Denham Golf Club He took a most enthusiastic interest in all the games at the medical school and was highly gratified to be elected president of the St Bartholomew's Athletic Club shortly before his death.

Theodore Just enjoyed his work as much as he did his leisure hours in the open air or at his home He infected his companions with his cheerful philosophy of which the memory will survive

Dr Geoffrey Evans writes: We who work at St Bartholomew's Hospital have lost a real friend in Theodore Just He came to us with a great athletic record and throughout his hospital career he maintained his keen interest in athletics He played for the hospital in the Rugby fifteen and won prizes in the inter hospital athletic sports more recently he occupied the position of president of the hospital athletic club He will be greatly missed *also in the masonic world* In 1930 he was Master of the Rahere Lodge and this year of his death he occupied the Chair of the Chapter We shall miss him in his professional work, which was of the highest order His natural simple manner endeared him to children and he *had already reached the first rank* in his special department as an aural surgeon To his contemporaries Theodore Just was a most lovable man and his nickname of Father Just gives an indication of his kindly way and the affection that was felt for him.

W S PAGET TOMLINSON M D Liverp F R C P Lond

Dr Paget Tomlinson's career as a medical practitioner ceased in 1880 when he succeeded to family estates But he remained both a student of medical affairs and an exponent of the medical outlook in local government and social service; and he leaves not only a fine record of devotion to duty but also a series of achievements that were essentially the fruit of medical experience

Born 88 years ago, the youngest son of Thomas Paget, he entered the Royal Infirmary School of Medicine at Liverpool in 1866, later going on to University College Hospital in London After a few months in Berlin and Vienna he settled in practice at Blundellsands, on the Mersey, and remained there 18 years, until the death of a relative brought him a change of home, of name, and—which was by no means welcome—of occupation He had to assume the functions of a Westmorland landowner, and within a few years he was High Sheriff of the county, but his interests were not confined to the more decorative offices or to his own estates He early joined the county council and was chairman at various times, and for long periods, of its agricultural and diseases of animals committee, of its school medical inspection committee, and of its public health committee His methods included persuasion by example thus he arranged, on his own account, for the dental care of every child in Kirkby Lonsdale for two years—an experiment demonstrating much better than mere words the necessity for appointing a county dental surgeon The 28 years during which he presided over the school medical inspection committee covered the development of the school medical service from nothing at all to a large organisation, he was, says one who worked with him, "an ideal chairman. To each of us he was like a father, full of interest in our work, happy and serene in his outlook on life" He was a keen naturalist, with special knowledge of birds, and he circulated among Westmorland school children a book he wrote for them, "Kindness to all Created Things" His liking for young people also led him to give his services to particular schools for a time he was a governor of Sedbergh, since 1908 he had been chairman of Queen Elizabeth School at Kirkby Lonsdale, and for 32 years he was chairman of Casterton School A more personal memorial however, is Meathop Sanatorium, the first tuberculosis sanatorium for the poor to be established in this country, which was opened in 1900 at the instigation of Dr Paget-Tomlinson and the late Dr W Rushton Parker This institution he supported largely from his own means, and many other local buildings and charities have benefited from his discerning generosity A musician and singer, he was choirmaster at the Kirkby Lonsdale parish church and a mainstay of the choral society A friend says of him that "he was the happy possessor of many gifts which he delighted to share with others"

Dr Paget-Tomlinson was elected a fellow of the Royal College of Physicians of London in 1927 and received the degree of LL D from Liverpool on the centenary of the medical school in 1934. He married, in 1874, Margaret, second daughter of Dr J Llewellyn Price of Standish The eldest of his sons died three weeks before his father, the survivors of the family are a daughter and two younger sons, one of whom is Dr E E Paget Tomlinson of Kirklington

ALBERT SOPHRON SIEGER, L.R C P Edin, D P H

The death of Dr A S Sieger on Feb 4th has removed from Clydeside one of the most popular figures in the shipping circles of the port of Glasgow Wherever he went in the course of his official duties as port medical officer he made friends and kept them, and this genial habit and his interest in yachting and cricket will not soon be forgotten

Dr Sieger was born in 1875 at Greenock where he was educated at the Glebe School and the Kilblain Academy, later he went to Glasgow to study medicine, and took the triple qualification in 1899 For some months he was engaged in general practice, but before the end of the year he was appointed senior civil surgeon to the military hospital at Devonport under Surgeon-General G Evatt, C B, M D, and served there until 1901 From Devonport he went to South Africa in the same capacity and was stationed at Kimberley, Wynberg, and East London in the last stages of the Boer War Returning to this country in 1902 he decided to devote his energies to public health work, and in 1903 he took his D P H at Edinburgh In December of the same year he was appointed assistant port medical officer under the Glasgow Port Local Authority, a post which he held for 33 years At the outbreak of the late war he was transferred to Ruchill fever hospital and later acted as superintendent of Shieldhall fever hospital Towards the close of 1915 he joined the R.A M C and was for a short time attached to the Redford Barracks at Edinburgh, then he went to Malta, and later to Alexandria, where he served as embarkation medical officer In 1919 he was demobilised with the rank of captain and resumed his service with the Glasgow Port Local Authority as port medical officer and, after 1920, inspector of aliens Dr Sieger was a prominent member of the Association of Port Sanitary Officers and had looked forward to the forthcoming meeting of this association at Glasgow with the arrangements for which he was actively concerned He leaves a widow and three children

JAMES MAXWELL WARNOCK, M D. Belf

Dr J M. Warnock, assistant medical officer of the Ards District Hospital, died at his home in Newtownards on Jan 31st He was a student of the old Queen's College, Belfast, and graduated in the Royal University of Ireland in 1906, taking his M D in 1910 After qualification, he worked for a time in Nottingham, and then settled in private practice at Newtownards He was appointed medical officer to the Union Infirmary on the death of Dr R C Parke in 1912, and by his conscientiousness and hard work earned the respect of medical men in the district A native of Kirkcubbin in the Ards peninsula, he was genuinely attached to the locality and its people, and he had a discerning taste for music The manner of his death bore testimony to his devotion to duty Falling a victim to influenza he was urged to take a holiday but refused on the grounds that he could not run away from his practice in the middle of an epidemic Soon after resuming work he took ill with broncho pneumonia and died within a few days He is survived by his wife, two sons, and a daughter

---

INTERNATIONAL HOSPITAL ASSOCIATION —The fifth International Hospital Congress will be held in Paris from July 5th to 11th Prof Roussy (Paris) will give a lecture at the first session on the care of the cancer patient in the hospital At the second session various aspects of hospitals and nursing in France will be dealt with, while at the third session there will be a discussion on how the hospital can increase its income and reduce its expenditure without detriment to its work At the fourth session the methodical organisation of hospital services will be considered, and the last two sessions will be devoted to short papers and discussions The secretariat of the congress may be addressed at the offices of the Direction Générale de l'Administration de l'Assistance Publique, 3, Avenue Victoria Paris IV, or through Mr Sydney Lamb general secretary 87, Lord street, Liverpool, 2

MEDICAL NEWS

University of Cambridge

The Raymond Horton Smith prize for the best thesis of 1935–36 has been divided between Dr Frank Goldby and Mr John Gray M Chir

The faculty board of medicine have coöpted Dr H Morley Fletcher and Prof F R Fraser as members of the board.

Royal College of Surgeons of England

A meeting of the council of the College was held on Feb 11th, with Sir Cuthbert Wallace the president in the chair Sir Charles Gordon Watson was appointed Bradshaw lecturer and Sir Charles Sherrington O.M was appointed Thomas Vicary lecturer for this year

Diplomas of membership were granted to W J C Crisp and to the candidates given in our issue of Feb 6th p 361 and diplomas in tropical medicine and hygiene to the candidates mentioned on p 362 Diplomas in medical radiology were granted jointly with the Royal College of Physicians to G G Binnie Frederick Constant Mary J Cronin and J M. Lees Diplomas in anaesthetics were granted jointly with the Royal College of Physicians under the special conditions of the regulations, to Harry Richards and R D Pramanik.

The following L.C C hospitals were recognised for the six months surgical practice required of candidates for the final fellowship examination: Dulwich St Giles Camberwell; St Olave s Rotherhithe Fulham St Leonard s, Shoreditch Mile End; St Alfege s Greenwich St Andrew s Bow; St James Balham Lambeth; Lewisham St Mary Islington St Charles Ladbroke-grove St Mary Abbot s Kensington Bethnal Green and Hackney but candidates who wish to qualify for admission to the final fellowship examination *by holding a resident post at one of the above* L C C hospitals are required to produce evidence of the suitability of such post before accepting the appointment

Conjoint Examining Board in England

The *following hospitals were added last year* to the list of institutions recognised by the Board:—

For the D.A —Kettering and District Hospital, North Middlesex County Hospital, West Middlesex County Hospital Oldchurch Hospital, Romford, County and City of Perth Royal Infirmary and Hospital for Sick Children Great Ormond street (under *special* conditions)

For the D C.H —Belgrave Hospital for Children, Clapham; Evelina Hospital for Sick Children, Southwark Hospital for Sick Children, Great Ormond street, Paddington Green Children s Hospital; Princess Elizabeth of York Hospital for Children, Shadwell, Queen s Hospital for Children Hackney Royal Waterloo Hospital for Children and Women South Eastern *Hospital* for Children, Sydenham Victoria *Hospital* for Children, Tite-street Alder Hey Hospital for Children Liverpool Booth Hall Hospital for Children Manchester; Jenny Lind Hospital for Children Norwich and St. Mary's Hospital Portsmouth

For the D L O —East Suffolk and Ipswich Hospital Radcliffe Infirmary Oxford Royal Hospital Wolverhampton and Royal Infirmary Doncaster

For the D O.M.S —East Suffolk and Ipswich Hospital; Royal Infirmary Doncaster and Sussex Eye Hospital, Brighton

For the D.P.M —Erdington House Birmingham

For the D T.M & H —Usher Institute Edinburgh

St Vincent Association

A house dinner will be held on Friday Feb 26th at 6.30 P.M., at the Old Cheshire Cheese Fleet-street London E.C Afterwards Mr Hector Hughes K C and Dr F W Crossley Holland will speak on some legal aspects of medical representation

Science and Building Exhibition

This exhibition which is to be held at the Building Centre 158 New Bond-street London W from March 1st to 25th *is being arranged by the Department of* Scientific and Industrial Research It includes exhibits by the Building Research Station the Forest Products Research Laboratory the National Physical Laboratory the Water Pollution Research Board the Department s Chemical Research Laboratory the Non Ferrous Metals Research Association, and other bodies Cinema films will be shown during the course of each day and lectures have also been arranged for certain evenings

University of Manchester

The following appointments are announced Dr P M. Crowe assistant lecturer in mental diseases; Dr F A. Gill special lecturer in mental diseases; Dr H. B May assistant lecturer in bacteriology; Mr H G Watkin, senior lecturer and clinical demonstrator in orthodontics; Mr A W Moule lecturer and demonstrator in clinical dental surgery Dr O H Adderley assistant bacteriologist in the routine section of the department of bacteriology and preventive medicine

Society of Public Analysts

A meeting of this society will be held on Friday March 5th at the Chemical Society's rooms, Burlington House Piccadilly W at 5 45 P.M at which Prof G Barger F.R.S will deliver an address on the alkaloids of ergot

Course in Psychological Medicine

The second part of the course of instruction for a diploma in psychological medicine which has been arranged by the London County Council and is being held at the Maudsley Hospital, Denmark Hill S.E will start on March 1st and continue till May 28th Further information may be had from Prof F L. Golla hon director of the medical school at the Maudsley Hospital

Post graduate Work at Aberdeen

A course of post-graduate study will be held at Aberdeen Royal Infirmary Forresterhill, and Aberdeen City Hospital *from April 20th till June 17th.* The lectures and demonstrations will be given at 3 15 P.M. on Tuesdays and repeated at the same time on Thursdays Further particulars may be had from the secretary of the University

Demonstrations of Contraceptive Technique

On Wednesday March 3rd at 2 30 P.M a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs Marie Stopes D.Sc. and Dr *Evelyn Fisher* Application for tickets from medical practitioners and senior students should be made to the hon secretary of the Society for Constructive Birth Control 108 Whitfield-street London, W 1

National Association for the Prevention of Tuberculosis

The 23rd annual conference of this association will be held in Bristol on July 1st, 2nd and 3rd The association may be addressed at Tavistock House North Tavistock square W C

Physical Recreation Committees

The Government has appointed a national advisory council and a grants committee for England and Wales in connexion with physical training and recreation The 31 members of the council include Lord Aberdare (chairman) hon. treasurer of the National Association of Boys Clubs the Hon Edward Cadogan, chairman of the Juvenile Organisations Committee of the Board of Education (deputy chairman); Mr Philip Noel Baker M P; Lord Burghley M P; Sir Noel Curtis Bennett hon. treasurer of the National Playing Fields Association Lord Dawson; Brigadier General Sir Wyndham Deedes Major A H A Gem organiser of physical training under *the* London County Council; Mr I D Innes D Sc chief education officer for Birmingham; Sir William Jenkins M P; Sir E K Le Fleming chairman of the Council of the British Medical Association Miss Margaret Morris, principal of the Institute of Margaret Morris Dancing Miss *Dorothy Round*; Miss I *Spafford* secretary of the Ling Physical Education Association and Mr W W Wakefield M P The first meeting of the council will take place on Wednesday March 3rd

The Grants committee will consist of Sir Henry Pelham (chairman) Mrs R C *Assheton* and Mr J C *Fuller* The secretary of both bodies will be Captain L. F Ellis to whom all communication should be addressed at Queen Anne s Chambers Tothill-street London S W 1

London School of Hygiene and Tropical Medicine

The annual malaria control course for laymen will be held at the school (Keppel street, W C) from June 21st to 25th under the direction of Sir Malcolm Watson The following additional lectures have also been arranged Mr H H Clay, water supplies (June 22nd at 2 15 P M), and conservancy and sewage disposal (June 23rd at 2 15 P M), and Dr G P Crowden, insulation against heat and cold (June 24th at 2 15 P M)

St Charles' Hospital, Kensington

On Feb 12th Lord Snell, chairman of the London County Council, opened the new nurses' home at this hospital Hitherto many of the nursing and domestic staff and two of the medical staff have been non resident owing to lack of accommodation Other arrangements were also unsatisfactory—the sitting room accommodation for nursing staff was inadequate lectures were held in a part of a ward partitioned off for the purpose, and there was no room for training probationers in practical work The new home, which accommodates 121 nursing and domestic staff, is a four storey building connected with the main administrative block by a paved footway All floors are served by a passenger lift The bedrooms are of the larger size decided on as a standard by the council in July, 1934, and each bedroom is fitted with a lavatory basin with hot and cold water and a built-in wardrobe cupboard For certain of the senior nurses a small sitting room is provided adjoining the bedroom Large common rooms are also provided for nurses and for sisters Bathrooms, shampoo rooms, tea making rooms, and box rooms are provided on each floor, and on the first floor there is a small laundry for the personal use of nurses There is also a lecture theatre, demonstration room and library for probationers Existing buildings have been adapted to provide accommodation for five assistant medical officers, the matron, and the assistant matron The total cost is about £38 425

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Infirmary—Hon Asst Physician

All Saints' Hosp , Austral street West square, S E—Res H.S at rate of £100

Army Dental Corps—Eight Commissions

Baghdad, Royal College of Medicine.—Prof. of Pathology, £150 per mensem

NOTES, COMMENTS, AND ABSTRACTS

MOVEMENTS OF THE DIGESTIVE TRACT

Dr **RUSSELL J REYNOLDS** delivered a Hunterian lecture at the Royal College of Surgeons of England on Jan 20th entitled "Movements of the Œsophagus, Stomach, Duodenum, and Ileum during the Passage of an Opaque Meal."

He explained that he would illustrate his remarks by cinematograph films made with an apparatus designed by himself, by which it was possible to obtain clear moving records of the image on a radiographic screen This method had the advantage that it perpetuated the whole of a radiographic examination instead of only chosen instants, so that the observer could study the record in detail afterwards The value of these films was strikingly demonstrated by the fact that the observer noticed new points every time he examined them. It was only necessary to expose a film for long enough to include several cycles of movement of an organ Any number of positives could be printed, and these could have their ends joined to form a circular band, which could be projected continuously as often as necessary

THE ŒSOPHAGUS AND STOMACH

On the fluorescent screen the image of the œsophagus appeared to be narrowed in three places at the upper end, where it was constricted by the inferior constrictor muscle of the pharynx, where it was crossed by the left main bronchus, and where it passed through the diaphragm It was dilated just above the diaphragm. During the act of swallowing, a bolus of food was projected to the back of the mouth by means of an upward and backward movement of the tongue A reflex action, stimulated by contact with the sensitive nerves in this area, caused the suprahyoid and associated muscles to contract, drawing the hyoid upwards and backwards and rotating it about a lateral axis The food was then jerked into the pharynx, which was attached to the hyoid and therefore drawn up with it The jerk carried the bolus over the epiglottis, which, with the raising of the hyoid, had closed the opening of the larynx The liquid then passed rapidly down under the influence of gravity, clinging to the sides of the œsophagus, which seemed to be dilated to receive it No peristalsis was visible On reaching the level of the clavicle the food was held up, either at the crossing of the left bronchus or by a weak sphincter where the muscle changed from a voluntary to an involuntary type

The food might then follow various courses Solid food was passed slowly down by peristalsis and went straight through the cardia as the wave of peristaltic relaxation reached the sphincter Semi solid food travelled in much the same manner, but liquid might act in one of three ways It might pass down in a thin stream under the influence of gravity, be held up at the cardia and fill the œsophageal ampulla like a test tube until the pressure was sufficient to open the cardia, the column then all entered the stomach at once Alternatively, gushes of fluid might pass rapidly down and enter the stomach directly without any delay at the cardia, this appeared to be due to the intermittent yielding of the intrathoracic sphincter Thirdly, the liquid might pass into the stomach in a constant thin stream under the influence of gravity In this case it was presumably allowed to escape through the constriction at the thoracic inlet at a constant rate, as it would be more likely to do if the constriction were purely mechanical, such as that caused by the left bronchus

After the food entered the stomach through the narrow cardiac orifice, it first passed into the upper part of the stomach, which comprised most of the fundus This part was passive, no peristalsis was observed, and it merely dilated against the normal muscular tone as it filled. It was separated from the more active lower parts of the stomach by a weak sphincter, which relaxed when a certain pressure was reached and allowed the food to pass through along the greater curvature When the lower part of the stomach was dilated, peristalsis began and passed the food along to the pyloric part Peristalsis caused a rise in pressure in the middle part of the stomach and the food regurgitated into the fundus General contraction forced the head of the food column through the pylorus into the duodenum The passage of liquid food through a stomach of good tone was rapid about 20 seconds from cardia to jejunum. In one of the films some of the opaque meal could be seen entering the jejunum while the last of it was still in the œsophagus

In the hypotonic stomach the three stages were not so well shown, but the passivity of the first part and the generalised contraction of the third seemed to be invariable The direct passage of the food out of a tonic stomach might be connected not only with the more vigorous movement, but also with the greater acidity of the stomach compared with the duodenum. The change in the character of the movement as the food passed through the stomach might depend upon the difference in the arrangement of the muscular coats In the first part of the stomach there were many oblique fibres and few circular In the second part, where the circular fibres were more numerous, peristalsis started, and in the third, where the circular coat was very thick and some of the longitudinal fibres interlaced with it, a generalised contraction took place The passage of food through the duodenum did not synchronise with the time of its escape from the stomach This might be due to the fact that the circular fibres of the stomach were not continuous with those of the duodenum, and the only fibres common to the two were a few longitudinal fibres not concerned with peristalsis When a tonic stomach was distended with food, very little mixing with the gastric juice or digestion or absorption of any kind could take place The food was hurried so rapidly through the duodenum that little digestion could occur there either, unless ordinary food were retained longer than the barium emulsion

The tonic and the hypotonic stomach alike contracted vigorously when they were suddenly distended with a large quantity of food After a short while the fibres lengthened and the stomach adapted itself to the bulk. Activity slowed down, and finally even the third part did not force enough barium meal through the pylorus to cast a shadow, but food was still passing rapidly through the duodenum 20 minutes after it had entered a tonic stomach Digestive trouble might possibly be caused by hurried meals because the stomach was given no time to adapt itself but was compelled to pass the food through insufficiently mixed with gastric juice

When the abdominal wall was relaxed, the whole stomach descended, except the pylorus, which was kept in position by the peritoneal attachments of the duodenum The coils of the small intestine, which before were supporting the stomach, descended into the pelvis and the stomach descended with them This gastroptosis kinked the stomach and formed a deep pool in which food might collect so that digestion was delayed and prevented. Moreover pressure on the veins and arteries might interfere with the blood supply A properly fitting abdominal belt would remedy the disturbance

When the emulsion entered the small intestine it soon became diluted with secretion and spread out so that the outline of the individual cells disappeared and the picture became indefinite The food moved rapidly through mainly in discrete *blocks by means of peristalsis*

'AS BIG AS A PIECE OF WOOD

SOME of us young or long memoried enough may recall receiving the above teasing reply from the grown up pestered by our oft-repeated question How big is it ? A moment s reflection showed us that the answer was unsatisfactory and our shrill questioning would soon begin afresh. Readers of the January issue of the *Journal of Pathology and Bacteriology* received a pleasant surprise in the form of an inset essay On the Quantitative Study of Tumours which shows that the clinical investigator like the difficult adult is still disinclined to give plain answers to plain questions. Rather than use a millimetre rule he prefers a vital system for has he not around him countless convenient measures from his own head, which is sometimes swelled to the head of a pin ? In the course of one paper the writer found tumours compared in size to ' a walnut a lentil, a pea a large pea a golf ball, a small hen s egg and a pigeon s egg Many of these obviously fall within the same unsatisfactory category as the piece of wood ; and with the golf ball there is the added danger of describing it as large or small which would inevitably lead sooner or later to friction between the Pathological Society of Great Britain and the Royal and Ancient Club two bodies who if never friendly have up to now always lived in mutual forbearance For the oölogical method of measurement there is more to be said though even this method is not free from objection. The range of size in eggs from the ostrich s on the one hand to the humming bird s on the other is wide enough for all ordinary tastes and when in doubt there is always the cuckoo s egg which apparently varies with the size of the egg of the foster-parent Nevertheless there are large and small eggs in every species and it must be remembered that a small hen s egg is not necessarily small The writer amusingly suggests that a standard egg might be kept in a strong room in the Houses of Parliament We should prefer the National Institute of Medical Research

WATER POLLUTION

AMONG the useful activities of the Water Pollution Research Board not the least is the preparation and issue of its Summary of Current Literature The January number of this monthly publication which starts the tenth year of issue contains 114 abstracts of papers and reports on subjects connected with water supply purification pollution sewage treatment It is of interest to note that French English and German processes have been patented for obtaining water from air either by condensation or absorption by hygroscopic substances and distillation of the absorbed water Another interesting observation is that the effect of rehousing in Leeds has not been to increase materially the per-capita consumption of water—the reason being it is suggested improvement in fittings and coöperation by consumers in prevention of waste It is recorded that the beet-sugar manufacturers of Belgium are alive to the necessity for prevention of pollution of water courses by effluent from their works and Belgium has a Ligue nationale contre la pollution des eaux

A good feature of these abstracts is that following the example of *Science Abstracts* they are numbered—a great assistance to the compilation of bibliographies and notes for reference

THE MIND OF THE YOUNG CHILD

AT a meeting of the Medical Society of Individual Psychology on Feb 11th Dr EMANUEL MILLER contributed the second of a series of lectures which form a symposium on mental health in childhood His subject was the development of the child from suckling to the fifth year

Dr Miller said that even by the time suckling is ended and the teeth have begun to appear an understanding of child behaviour can only be fully understood by considering both biological and psychological processes With the emergence of the teeth the appetitive instincts of the child take on a special quality because the development of the muscles of the jaw develops in conjunction with other muscular coördinations For example, the child is beginning to grasp more skilfully and the satisfaction of hunger is in the nature of an attack on the desired object the food. At this stage we can still say that this act is primarily in the nature of desire rather than the operation of what is sometimes called primary aggression. Aggression can only be said to come when the child's instinctual needs are frustrated. At the same time different parts of the body are involved in acts of instinct ; gratification and pleasure feelings no doubt accompany these acts and make them additionally worth while. It is natural for a child to feel frustration because the manner in which its life is managed does not always keep pace with the natural rhythms in the ebb and flow of the child s appetites. The child now begins to feel a difference between itself as *me* and an obstinate external world which is merely felt as a *not me* This *not me* is the source of privation which the child dreads The facial expression and bodily movements of a child of this age indicate that dread and privation seem to go together The mother or nurse is the first environmental influence which is felt as a source of gratification and of privation In the *same way as a* child assimilates its food so it assimilates this first person into itself This is the first phase of the process of introjection of the parent s figure When the child has begun to walk, it meets other forms of frustration which usually originate in those who satisfy its needs and who govern its needs The child controls *or* restrains itself in regard to its instincts by taking into itself those very persons who have restrained it It assimilates them. Thus within the mind of the child there develop good and bad images of the parent figures. The mother internal image is more likely to be in a normal case a kindly image than a bad one but as it grows older this good or bad *or* both images is now set over against the real parents whom the child sees as a figure of its external objective world. Any angry feelings born of frustration are as likely to be directed against the image parent as the real one and the *child is* constantly testing external experience to see whether it conforms to its new internal estimates of the parents This can give rise to refractory behaviour and anxiety anxiety to control instinctual impulses at one time or playing up to reinstate a pleasant good relationship with *the* parent by being good or by being babyish

This being babyish may appear in behaviour as a sudden return to infantile modes of response Having introjected the restraining parent images the child may develop a fear of those bodily functions and organs which have been restrained or controlled ; thus a child may become constipated through fear of dirtying or refuse to eat or may express fears indirectly about micturition and the organ associated with it By the eighteenth month the growth of intelligence and language gives the child an instrument for controlling the external world and this becomes in a way an escape from instinctual pressure His verbal behaviour therefore enables it to disguise its instinctual needs by verbal manipulations, frequently projecting upon the external world a verbal expression of its anxieties The next year or so is concerned with attempts to understand not only the external world in general but the parents in particular The double feelings it has about parents are intermittently solved by giving all love to one and showing hostility to the other This mood oscillates and may be disquieting to parents, but if the parents can meet the situation with equanimity the child gradually gets assured that its hostility is an internal thing and not " just to " external facts In fact, the child is trying to project its inner hostility of the outer world for purposes of release, and it should be given every opportunity through play to obtain this release and by contact with persons other than parents to diffuse love and hostility over a wider field

WOMEN DISTRESSED IN MIND

THE council of the Society of the Crown of our Lord, commemorating and carrying on the work of its foundress, Miss Bertha James, who died last year, wishes to provide for educated women whose mental health is temporarily impaired the advantages of skilled medical treatment together with nursing and spiritual help To this end an appeal has been issued to which Lord Dawson of Penn and Sir Francis Fremantle among others have put their names A sum of £3000 is being sought for the purchase and equipment of a house which would in effect become an inexpensive nursing-home with a religious atmosphere The Society proposes to allot the largest rooms at four to five guineas a week, the remainder at much less It is certain that there are many patients who would benefit greatly from a stay in such a home especially if care be taken, as no doubt it will, to select them judiciously on psychiatric as well as other grounds We gladly endorse the appeal

Appointments

BETTLEY F R M D M R C P Lond has been appointed Hon Dermatologist and Medical Officer in Charge of the Male Venereal Diseases Centre at Cardiff Royal Infirmary

BURN J L M.D Durh D P M Medical Officer of Health for Barnsley

THE Index and Title page to Vol. II, 1936, which was completed with the issue of Dec 26th, is now ready A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now

ADDRESSES AND ORIGINAL ARTICLES

TUBERCULOSIS IN RELATION TO LIFE ASSURANCE *

BY OTTO MAY, M.D Camb F.R.C.P Lond
PRINCIPAL MEDICAL OFFICER TO THE PRUDENTIAL ASSURANCE COMPANY LONDON

IN essence life assurance is a system of pooling resources by a group of individuals in order to pay out a sum at death or after a certain period The annual premiums are calculated on certain mortality tables which show how many of the group may be expected to die each year

Most of the tables at present in use are select ones based on groups of people specially selected by careful inspection of a completed proposal form usually supplemented by a medical examination The latest table of this type, compiled by the Institute of Actuaries, and known as A 1924–29 Ult is based on the mortality between those years of persons accepted by various British companies as first class risks It shows, for each age, the mortality rate for each of the first three years after entry and subsequently for attained ages regardless of the age at entry The Chart shows what this latter rate is for lives aged from 30 onwards (dotted line) In the first year it is about 0 0025 and it rises only very gradually till after 23 years it reaches 0 01 (1 in 100) The continuous black line shows the mortality (males) from the English census returns of 1921 and is slightly higher though roughly parallel to the former

Types of Impairment

Suppose now that we have to consider how to deal with a group of proposers in whom there is some definite impairment some condition likely to upset the mortality curve Such conditions are of various types, which may be classified as follows —

(1) Occupational risks, of which the most important in life assurance is the retail trade in alcoholic liquors.
(2) Climatic risks
(3) Family history
(4) History of past illnesses
(5) Impairment in personal condition

Of course the same proposer may have impairments in more than one of these classes—e g. a publican with a tuberculous family history and a bad health record of his own

From the actuarial point of view the ideal way of assessing the extra risk in a particular case would be to construct from an experience of a large number of similar cases the mortality curve and to calculate from this how best to meet the extra risk thus shown Unfortunately for a large proportion of impairments the necessary data are too scanty to allow of this method and in such cases the method of dealing with the impairment must be largely empirical. There are various plans in use for accepting impaired lives at special terms the chief being—

(1) An addition of years to the age at entry so that the proposer pays an extra premium equal to the difference between that at his actual age and at the rated up age

(2) Similarly a certain extra sum may be added to the premium either for a limited period or for the duration of the policy not necessarily corresponding to any special age

(3) A reducing debt or lien is imposed usually a percentage of the sum assured which lien is reduced each year until it is wiped out For example in the case of a policy of £1000 the lien might be £500 reducible each year by say £25 until after 20 years the lien is extinguished

As to which is the most suitable from the actuarial point of view a great deal depends upon the nature of the extra risk. Some are definitely *increasing* risks such as the presence of some cardiovascular defect or excessive weight or a bad family history of cardiovascular disorders ; some are more or less *constant* such as climatic or occupational risks while others are definitely *decreasing* such as a personal history of pulmonary tuberculosis underweight &c An increasing or constant risk is best covered by an addition to the premium or rating up of the age while a decreasing risk is suitably met by a reducing lien which gradually disappears as the risk diminishes

From the proposer's point of view this method makes no appeal when the object of the insurance is primarily protection—i e when cover is definitely required in case of early death When on the other hand, the investment factor is of importance, such as provision for old age he would regard the lien as the preferable way as he pays no extra and should he survive a certain period, he receives the full face value of the policy

Impairment from Tuberculosis

Having given this preliminary sketch of life assurance in general I should now like to indicate how the tuberculosis problem is regarded in present-day life assurance practice I shall not discuss any of the questions of diagnosis, prognosis or treatment but merely indicate how the business of life assurance regards the various aspects of this problem Our methods may seem grossly empirical and unscientific, but it must be borne in mind (1) that the premiums charged allow only a small margin for medical expenses and (2) that competition between companies is pretty keen, and tends to prevent a too scrupulous investigation of apparently unimportant points For these reasons cases must be assessed on information which is often scrappy as regards both family history and past history and which is not seldom unreliable even on the question of the personal examination of the proposer Unless the proposal is for a large amount, it is usually impracticable to have the examination conducted by a specialist and the questions of expense and competition often prohibit a radiogram of the lungs or even a sputum examination in cases in which these methods might be regarded as indispensable in clinical practice In cases in which a past history of pulmonary tuberculosis figures on the proposal a report from the proposer's own doctor often draws a blank as the proposer may have received institutional treatment, and the practitioner seems unable or unwilling to give any useful information to the company Of course it is open to the latter to insist on the proposer giving the name of the institution with permission to apply to the medical superintendent for a report, but unless the proposal is for a substantial amount the cost of the examination and of the doctor's report already incurred together with the further delay involved may cause the company to assess the case on the information already in their possession instead of pursuing the matter any further

FAMILY HISTORY

Two large actuarial investigations on the influence of family history on pulmonary tuberculosis are worth mentioning, the first by Rusher and Kenchington (1913) and the second by the American Medico-Actuarial Investigation Committee (1914) Without going into details, both these confirmed the fact of the adverse influence on mortality of a family history of one or more cases of pulmonary tuberculosis, especially on *young, underweight* proposers If the young proposers are, in addition, *tall* (5 ft 11 in and upwards), the excess mortality is greater than for shorter underweights Incidentally the American investigation brought out clearly in this group an interesting point—namely, the decreasing proportion of deaths from tuberculosis with increasing weight, and increasing age This is shown in Table I

---

* An address to the Tuberculosis Association delivered on Feb 20th

TABLE I

Effect of Weight and of Age

Weight	Age at entry 15–29			Age at entry 30–44		
Deviation from standard in pounds	Total deaths	Deaths from phthisis	Ratio (%)	Total deaths	Deaths from phthisis	Ratio (%)
−45 to −25	59	31	53	302	93	31
−20 to − 5	658	294	45	911	198	22
0 to +20	475	134	28	670	65	10
+25 to +45	71	5	7	216	4	2

In America, where the "numerical rating system" is almost universal, the extra mortality for family history is assessed on the lines shown in Table II, the amount depending on age at entry and the degree of deviation from the average weight for age In this connexion a further point may be mentioned To the tuberculosis expert, the interest of family history is principally on the question "How far, if at all, is the disease an hereditary one?" To the insurance company, the point of interest is "Does a tuberculous family history tend to impair the expectation of life—i.e., to increase the mortality risk?" They are not specially interested in the causes of the extra deaths, be they tuberculosis, diabetes, or anything else, but only in the fact of extra deaths in the group in question

CONTACTS

Here we arrive on debatable ground. The problems of marital infection and the analogous risks in family circles have been hotly debated At present there appears to be a predominating opinion that close contact in insanitary surroundings is a definite risk. A recent paper by Lloyd and MacPherson (1936) confirms this in the case histories of young adults with pulmonary tuberculosis, although, in the great majority of cases investigated by them, the contact was with tuberculous members of their families, so that the question of contact is complicated by that of heredity or familial susceptibility This point was emphasised as long ago as 1908 by Pope He found that the probability of infection between husband and wife was considerably less than between parents and child, or brother and sister, a result suggesting that hereditary "lack of resistance" plays a large part in many of the cases of apparent direct infection Whatever may be the theoretical truth regarding contact and hereditary predisposition, most insurance companies impose some extra if the proposer has been living in the same house as a patient with open tuberculosis, the amount of the extra depending on the hygienic conditions of the case and the various other obvious factors, such as proposer's physique and family history With my company it is customary to impose a fairly heavy reducing lien if there has been contact within 12 months of proposal, with an offer to reconsider the terms in a year on medical examination In America, "contact" is usually regarded for insurance purposes as equivalent to a family history of tuberculosis

PERSONAL HISTORY

When, if ever, is it practicable to undertake the insurance of proposers with a personal history of pulmonary tuberculosis? I need hardly point out that the mortality in the early years *after treatment* is high, even in the case of those who came under treatment at a comparatively early stage of the disease Among those applying for life assurance, with a history of pulmonary tuberculosis, the larger proportion are naturally in this group, though such is the optimism of the sufferer, or perhaps of the agent, that we not very rarely receive proposals from tuberculous patients in an advanced stage of the disease

Two English medico actuarial investigations of the after histories of patients who have been under sanatorium treatment are very instructive for the insurance offices, and I should like to refer to them in this connexion, they are those from Midhurst and Frimley The excellent annual reports from Midhurst (1935) contain a statistical record of all the cases discharged from the sanatorium since 1906, arranged in various groups according to the condition on admission, and presence or absence of tubercle bacilli in the sputum during their stay The total number discharged is 6451, and only 224 (or 3 4 per cent) cannot be traced

TABLE II

Rating for Build with or without Family History of Tuberculosis

Ages	No of cases of T B	Pounds under or over weight						
		−41 to −56	−25 to −40	−9 to −24	−8 to +8	+9 to +24	+25 to +40	+41 to +60

	1	50	30	20	10	10	20	30
	2	100	60	40	30	20	20	30
	3	R	100	70	60	40	35	60
33–37	0	15	0	0	0	0	20	Rate for build alone
	1	30	15	10	0	0	20	
	2	70	40	30	20	10	25	
	3	110	70	50	40	25	40	
38–42	0	5	0	0	0	0	25	
	1	15	10	0	0	0	25	
	2	50	30	20	20	10	25	
	3	75	50	30	30	20	30	
43–47	1	10	0	0	0	0	25	
	2	30	20	20	0	0	25	
	3	50	30	20	20	10	30	
48	1	0	0	0	0	0	25	
	2	0	0	0	0	0	25	
	3	20	0	0	0	0	25	

Plus 50 means a mortality of 150 instead of the expected 100
R = rejected

The Chart shows the mortality experience (1) of *all* discharged cases (Curve E) and (2) mild cases only (Curve D) or Group 1 (Turban Gerhardt) T B positive —cases in which bacilli have been found—which have

> disease of slight severity limited to small areas of one lobe on either side which in the case of affection of both apices, does not extend beyond the spine of the scapula or the clavicle in the case of affection of the apex of one lung, does not extend below the second rib in front

The actual figures produce an irregular line due of course to the relatively scanty data. I have had this graduated into a smooth curve which to the actuary is an approximation to what might be expected if the data were large enough A comparison of these with the curves A and B of first-class risks (A 1924–29 and E.L.T 9) in males from age 30 shows the enormous excess mortality in the early years In the first year after discharge Curve E shows a mortality approximately 50 times the expected, and even after 5 years it is still about 25 times that expected from A (A 1924–29) after 10 years it is roughly 12 times after 20 years about 4 times and only after some 25 years do the two curves show signs of approximation Curve D the mild cases shows, as would be expected, a rather less unfavourable mortality In the first year it is roughly 17 times the expected after 5 years about 12 times after 10 years about 8 times and after 20 years about 3 times.

The Frimley experience deals with the patients admitted between 1905 and 1931 and comprises 8766 patients (Hartley Wingfield and Burrows 1935). For comparison with the Midhurst experience, I have taken the group of Grade B1 males

> All being T.B positive cases with slight constitutional disturbances, if any The obvious physical signs should be of very limited extent as follows Either present in one lobe only and in the case of an apical lesion of one upper lobe not extending below the second rib in front and not exceeding an equivalent area in any one lobe; or where these physical signs are present in more than one lobe they should be limited to the apices of the upper lobe and should not extend below the clavicle and the spine of the scapula No complication (tuberculous or other) of prognostic gravity should be present A small area of dry pleurisy should not exclude a case from this group

It will be seen that this group is very similar to Group 1 in the Midhurst classification and the mortality table here worked out in Curve C shows a general resemblance to that already shown for Midhurst (Curve D)

We may assume therefore that we have a pretty clear view of the mortality of a considerable group of cases having these features (1) all T B positive (2) all having undergone sanatorium treatment (3) physical signs as defined above—i e limited to infiltration or catarrh of one lobe or small parts of two—(4) without grave complications These constitute what one is prone to regard as a favourable type of case and yet the mortality compared even with the general population shows an enormous though decreasing excess for at least 20–25 years after discharge

Effect on Insurance

Suppose there were a scheme of compulsory insurance for this group it is I think obvious that the premiums to cover the risks would have to be so enormous as to make them fantastic It is the early incidence of the risk that makes this inevitable—reverse the extra mortality into an increasing risk, and the problem would be less insoluble

If however instead of extra premium the method of a decreasing lien is considered it will be seen that the situation is more promising Even two years after discharge, cases of this type might be accepted with a very heavy reducing lien say 80–90 per cent especially if proposing for an endowment assurance

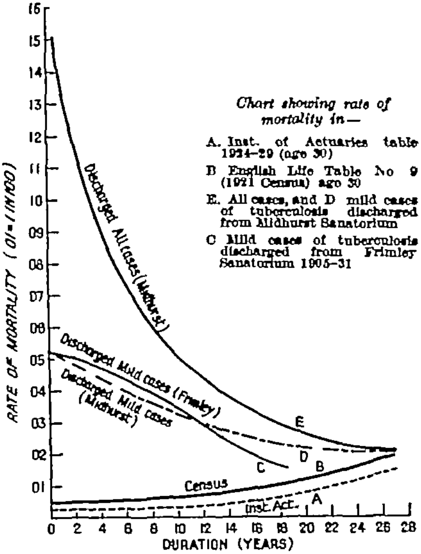

Chart showing rate of mortality in—

A. Inst. of Actuaries table 1924–29 (age 30)

B English Life Table No 9 (1921 Census) age 30

E. All cases, and D mild cases of tuberculosis discharged from Midhurst Sanatorium

C Mild cases of tuberculosis discharged from Frimley Sanatorium 1905–31

Naturally the death cover is very small at first and such a policy has little value as protection for dependants but sufferers from pulmonary tuberculosis can hardly expect it If they care for a policy that is primarily an investment this can be achieved by the offer of an endowment with a heavy lien My company has issued many such policies usually with an offer to reconsider the amount of the lien after the lapse of a few years and I cannot help thinking that these play a useful part from the psychological point of view It surely must help a tuberculous patient to a greater confidence in his future if he finds that a company is willing to offer him an insurance contract even though the death benefit is small.

Recently my company has investigated their experience of a group of entrants 1921–23 (three years) who all had a personal history of tuberculosis (nearly half being pulmonary) and who had been accepted under the conditions outlined above They numbered 804 of whom 353 were pulmonary cases Of the 804 79 died in the first 12 years of insurance against an expected 42; of the 353 pulmonary 47 died against an expected 17 This shows that the selection of cases was reasonably good. The actual claims paid in the group amounted to £11 506; the 'expected according to A 1924–29 would have been £11 017—a result indicating that this method strikes a fair balance between the proposers and the company

Special Cases

You will have noticed of course that I have discussed the insurance of these cases in bulk and said nothing about methods of individual selection. As I have indicated above, unless the proposals are for fairly large sums, it may be impracticable to investigate them as thoroughly as one would like to do, though personally I should never accept any proposal with a T B plus history, during the first five years without a heavy rating, however free from symptoms or physical signs he may appear to be

ARTIFICIAL PNEUMOTHORAX

I should be glad to hear medical opinion on how far treatment by artificial pneumothorax is to be regarded as a favourable prognostic feature Judging by the Frimley report, this method is used hardly at all in mild (Group B1) cases It was performed chiefly (in over 80 per cent) in Group B3 " Cases with profound systemic disturbance or constitutional deterioration, with marked impairment of function, either local or general, and with little or no prospect of recovery " These cases, when compared with other groups of the same sex, age group, and medical grade on admission, showed a more favourable mortality, suggesting that in these comparatively advanced cases it improved the period of survival We receive proposals from quite a considerable number of patients either with a history of artificial pneumothorax treatment, or even still having periodical refills, but I can give no figures of comparison with other cases We seldom find it practicable to consider these on more favourable terms, as the evidence of a definitely better prognosis is still rather scanty As regards other methods of treatment, such as phrenicotomy, thoracoplasty, and oleothorax, the number of próposals is small, and of course the cases are usually those in which the disease has been severe, so that it could hardly be expected that the terms of acceptance would be more favourable

NON PULMONARY TUBERCULOSIS

I have discussed the acceptance of pulmonary cases in some detail, and what has been said in that connexion applies, more or less closely, to urogenital tuberculosis No case would be accepted within five years of the disease, except with a maximum lien, and from five to ten years the lien should be a substantial one

In tuberculous joint or bone disease and adenitis we do not, as a rule, take such a grave view as in genito urinary and pulmonary disease, each case is treated on its merits, with regard to family history, age, physique, occupation and, of course, the extent of the original infection, and the time elapsing since then

PLEURISY

A history of primary pleurisy, whether dry or with effusion, is for assurance purposes always regarded as probably of tuberculous origin It is my usual practice to impose some lien in every case with this history till at least seven years have elapsed the amount of the lien varies according to the time, family history, physique, and so on It may be as little as 20 per cent. (our minimum) In our investigation of 2040 cases accepted in 1921–23, the actual deaths numbered 209, against the " expected " (A 1924–29) of 159 as regards the amount of claims, the " net " actual was £37,400 against the ' expected " of £46,475, a fairly substantial surplus, which is largely distributed as bonus to the survivors

In the " Medical impairment mortality ratings," which are used in America for their numerical method of assessment, no case is considered until at least a year after the attack The " extra " imposed after that period varies according to whether the attack was dry or with effusion, and according to the duration of the attack (dry), whether less than or more than two weeks, and according to the period that has elapsed, the age of the proposal, and the weight/height ratio

TABLE III

Dry Pleurisy (Attacks of less than 2 weeks)

50	+10	+ 5	+ 5	+ 0	+ 0	+ 0	+ 0
55	+ 5	+ 5	+ 0	+ 0	+ 0	+ 0	+ 0

It should be noted that the ratings here given are independent of and in addition to those which normally apply on account of the build of the applicant

Table III is an example of their method for assessment of an attack of dry pleurisy lasting less than two weeks It will be seen that the extra mortality rating varies from + 70 for young underweights in the second or third year after attack, to 0 in elderly people of normal weight or over For a longer attack (over two weeks) the corresponding maximum is + 140

Conclusion

In conclusion I should like to emphasise once more that the life assurance attitude towards tuberculosis is inevitably one of grouping cases into classes for which some sort of mortality table has been calculated, or can be presumed, rather than of considering them as clinical individuals

It is probable, nay certain, that some cases are dealt with too harshly, and others too leniently, but I see no way of avoiding this state of affairs If any one can point out any simple means of more exact prognosis in individual cases, I for one will welcome the information, and use it so far as is practicable for a more equitable assessment of the terms of acceptance in these cases

THE TREATMENT OF IMPERFECT DESCENT OF THE TESTIS WITH GONADOTROPIC HORMONES

BY T W MIMPRISS M.S Lond. F R C S Eng
CHIEF ASSISTANT IN THE SURGICAL UNIT ST THOMAS'S HOSPITAL, LONDON

FOR several years gonadotropic hormones have been used in the treatment of imperfect descent of the testis At present this method of treatment is still in the experimental stage, and it is probable that more prominence is given to the successes than to the failures of treatment. Few contra indications appear to be recognised and the method is too recent to permit any investigation into the possibilities of late complications

Schapiro (1930) reported a series of successful cases and various publications chiefly by American authors have appeared since On the whole the articles on this subject suggest that the treatment is successful in a high proportion of cases and that it is at any rate, harmless and should be tried On the other hand Cabot (1936) a recognised authority on the treatment of imperfect descent of the testis lecturing at St Thomas's Hospital in September 1936 considered treatment with gonadotropic hormones as unsatisfactory and possibly harmful The experience of this method in the surgical unit at the hospital over the last two years tends to support this view

THE MATERIAL

This paper gives an account of the results obtained by this method in 20 cases of imperfect descent of the testis which I have treated between May 1935 and December 1936 These patients, with the exception of 3 under the age of five represent the whole number which were kindly referred to me by the staff of St Thomas's Hospital and no selection of cases has been practised since in May 1935 there were no well recognised indications or contra-indications to the use of gonadotropic hormones

There had been no previous treatment in 14 cases but the remaining 6 had been the subject of unsuccessful operations The preparation used was Pregnyl (Organon Laboratories) and it was administered intramuscularly into the buttock in doses of 500 rat units Injections were usually given twice weekly but in some cases only one a week was given.

RESULTS

The following case summaries show the original condition and the results of treatment in the 14 patients who had had no previous treatment and in those who had had unsuccessful orchidopexy operations

PATIENTS WITH NO PREVIOUS TREATMENT

CASE 1—Aged 10 Bilateral imperfect descent of testes Orchidopexy performed on right at the age of 8 Small left testis in inguinal canal; right testis high in scrotum; small genitalia

Result—(18 injections) Both testes now in scrotum; development of genitalia better

CASE 2.—Aged 9 Bilateral imperfect descent of testes both in inguinal canal; small genitalia

Result—(12 injections) Both testes now in scrotum development of genitalia better

CASE 3—Aged 13 Bilateral imperfect descent of testes; both in inguinal canal; small genitalia

Result—(10 injections.) Both testes now in scrotum; development of genitalia better

CASE 4—Aged 6 Imperfect descent of right testis which was at external ring left descended late and sometimes retracts; small genitalia

Result—(10 injections) Both testes now in scrotum development of genitalia better

CASE 5—Aged 12 Bilateral imperfect descent of testes both in inguinal canal small genitalia

Result—(40 injections) Hypertrophy of genitalia no descent

CASE 6—Aged 14 Bilateral imperfect descent of testes both of good size outside external ring genitalia well developed

Result.—(21 injections.) Hypertrophy of genitalia no descent

CASE 7—Aged 15 Bilateral imperfect descent of testes A satisfactory orchidopexy performed on the left side at the age of 12 Right testis at the external ring genitalia well developed.

Result—(14 injections) Hypertrophy of genitalia no descent

CASE 8—Aged 12 Bilateral imperfect descent of testes Very small genitalia; testes not palpable Fröhlich type

Result—(25 injections) Testes not palpable; penis and scrotum larger growth of pubic hair

CASE 9—Aged 10 Imperfect descent of right testis, in inguinal canal genitalia well developed

Result—(16 injections) Hypertrophy of genitalia; no descent

CASE 10—Aged 12. Imperfect descent of right testis in inguinal canal genitalia well developed

Result—(21 injections.) Hypertrophy of genitalia; no descent

CASE 11—Aged 6 Imperfect descent of left testis, at external ring; genitalia well developed

Result—(18 injections) Gross hypertrophy of genitalia no descent

CASE 12—Aged 12. Imperfect descent of left testis outside external ring; genitalia well developed

Result—(20 injections) Hypertrophy of genitalia; no descent

CASE 13—Aged 14 Imperfect descent of right testis at external ring genitalia well developed.

Result—(15 injections.) Hypertrophy of genitalia; no descent

CASE 14—Aged 5 Imperfect descent of left testis, in inguinal canal; genitalia well developed

Result—(8 injections) Hypertrophy of genitalia no descent

AFTER UNSUCCESSFUL ORCHIDOPEXY

CASE 15—Bilateral imperfect descent bilateral unsuccessful orchidopexy at 9 years

Injection treatment at 11 years; testes over pubes genitalia very small.

Result—(10 injections) Development of genitalia; descent of testes.

CASE 16—Bilateral imperfect descent bilateral unsuccessful orchidopexy at 8 years

Injection treatment at 11 years; right testis over pubis; left at external ring; genitalia very small.

Result—(30 injections) Development of genitalia descent of testes to scrotum

CASE 17—Bilateral imperfect descent bilateral unsuccessful orchidopexy at 5 years

Injection treatment at 11 years; both testes at the external ring and size of a pea genitalia very small

Result—(30 injections) No change

CASE 18—Imperfect descent of left testis; unsuccessful orchidopexy at 7 years

Injection treatment at 12 years; small left testis over pubis; genitalia otherwise normal.

Result—(16 injections) Hypertrophy of genitalia; no descent

CASE 19 —Imperfect descent of right testis, unsuccessful orchidopexy at 4 years
Injection treatment at 6 years, right testis at external ring, genitalia well developed
Result —(12 injections) Hypertrophy of genitalia, no descent

CASE 20 —Imperfect descent of right testis, unsuccessful orchidopexy at 12 years
Injection treatment at 15 years, minute right testis at external ring, genitalia normal
Result —(8 injections) Hypertrophy of genitalia but right testis was unaltered in size and position

COMMENTS

Of the 14 cases that had had no previous treatment 4 have been successful Cases 1, 2, 3 were suffering from bilateral and Case 4 from unilateral maldescent In all 4 the most noticeable feature was the under development of the external genitalia—i e, the testes, penis, and scrotum—before treatment commenced In each case the injections of pregnyl caused hypertrophy of the external genitalia, followed by descent of the testes

The remaining 10 cases were unsuccessful, 4 of these were bilateral. Case 5 appeared similar to Cases 1, 2, and 3, so treatment was persevered with It has now been stopped as the external genitalia have hypertrophied without descent of the testes Cases 6 and 7 both had well developed genitalia when first seen and treatment was stopped in view of the further hypertrophy observed. Both have had satisfactory Torek operations since and in each case it was found that the testis had emerged from the external ring in front of which it was lying The presence of retaining fibrous bands showed that no treatment other than operation would have been of any use in these two cases The other bilateral case (Case 8) was of the Fröhlich's type and although there is slight enlargement of the penis and scrotum and a thin growth of pubic hair, there is still extreme hypoplasia of the genitalia and the testes cannot be palpated

The remaining 6 cases were all unilateral and in all the genitalia were well developed before treatment commenced Pregnyl injections have in each case produced hypertrophy of the penis, scrotum, and both testes, but no descent of the retained testis, and because of this hypertrophy the treatment has been abandoned

In the second group (after unsuccessful orchidopexy) there were two successes, which had both been the subject of bilateral Bevan operations In both the genitalia were very small and the scrotum in particular was very badly developed. In each the course of pregnyl injections has produced hypertrophy of the whole genital apparatus and descent of the testes into the scrotum The increase in size of the testis and the greater development of the scrotum seem to be the factors which cause descent The other patient with bilateral imperfect descent of the testes in this group (Case 17) had undergone an unsuccessful Bevan operation on both sides The genitalia were very small and the testes appeared to be atrophied The injections of pregnyl have produced no change in relation to development of the genitalia or descent of the testes and it is probable that the blood supply of the testes was interfered with at operation The other three cases were all unilateral and in two (Cases 18 and 19) hypertrophy of all the genitalia, without descent of the retained testis occurred A further operation of the Torek type is advised for these cases In Case 20 the treatment produced hypertrophy of the genitalia with the exception of the imperfectly descended testis, this is very small and has probably had its blood supply interfered with

THE INDICATIONS FOR THE USE OF GONADOTROPIC HORMONES

In this small series one result of this method of treatment is very evident—the hypertrophy of the genital apparatus, i e, the penis, scrotum, and testes, In a few cases there was also growth of pubic hair Only one patient has failed to show hypertrophy (Case 17) and he probably has atrophic testes after a previous unsuccessful operation The one patient of the Fröhlich's type (Case 8) has shown little change but injections will be continued after two months' rest

This question of hypertrophy of the external genitalia, including the penis and scrotum, is obviously of importance, yet certain authors make no mention of this in their reports on the use of gonadotropic hormones

Spence and Scowen (1935) state that in several of their cases there has been some enlargement of the testes during treatment, and in a few slight enlargement of the penis and growth of the pubic hair McLellan (1936) states that the undescended testis becomes larger, heavier and more mobile, but makes no reference to general enlargement of the genitalia, and elsewhere he states that no harm can be done by a trial of this treatment Webster (1935) reports 10 good results out of 11 cases treated by gonadotropic hormones, and mentions only that enlargement of the imperfectly descended testis occurred

On the other hand, Goldman and Stern (1933), Sexton (1934), and Aberle and Jenkins (1934) have all noted, in some cases, enlargement of the whole external genitalia as a result of treatment with gonadotropic hormones

In this series every case except Case 17 has shown definite hypertrophy of the genitalia In one, Case 11, gross hypertrophy occurred and in the majority the treatment was stopped for this reason

I consider therefore that injection of pregnyl is much more likely to produce genital hypertrophy than descent of a retained testis and that this should be borne in mind by anyone advocating this method of treatment I now endeavour to select those cases that are suitable for hormone therapy, as I feel that there are definite objections to the treatment

From the point of view of treatment with gonadotropic hormones, the cases can be grouped as follows

A. *Bilateral imperfect descent* —1 With well-developed genitalia and the testes probably retained owing to some mechanical cause Case 6 is a good example of this type The effect of pregnyl here is to produce hypertrophy and not descent, and in my opinion operation is the only treatment In this group I place Cases 6 and 7

2 With poor development of the whole genital apparatus Pregnyl here will produce development of the whole genitalia and the increase in size of the testes and scrotum may allow the natural position to be gained Of the 6 satisfactory cases 5 come into this group (Cases, 1, 2, 3, 15, and 16) Case 5 also belongs to this group, but descent has not occurred

3 Associated with Fröhlich's disease Here pregnyl also seems indicated, although in my own case (Case 8) no success has as yet been attained

B *Unilateral imperfect descent* —In nearly all cases the other testis and the penis are reasonably developed, since hypertrophy will occur I think pregnyl should never be employed in *unilateral maldescent of the testis* Case 4 is listed as a success, but as the scrotal testis had descended late it is possible that descent and normal development would have occurred spontaneously

C *Testes which are definitely ectopic in position* —Spence and Scowen have pointed out that on anatomical grounds the method cannot succeed

In our present state of knowledge there are obvious objections to the indiscriminate use of these prepara-

tions which produce genital hypertrophy Cabot (1936) has referred to the possibility of late atrophy of the testes; Cole (1936) has produced atrophy of the tubules in experimental animals by high dosage Evans is quoted by Goldman and Stern (1936) as having produced damage and ultimate decrease in weight in the testes of rats In this series Case 11 showed gross hypertrophy of the genitalia at the termination of treatment Three months later considerable retrogression in size had occurred and at the subsequent operation to fix the testis in the scrotum the testis was found to be very small. Goldman and Stern (1936) and other authors have commented on the possible development of precocious sexual maturity and this must be accepted as another definite risk of the treatment For this *reason they and Engle (whom they quote)* consider nine as the earliest age at which treatment with gonadotropic hormones should be started.

The present position therefore is that injection of gonadotropic hormones will produce hypertrophy of the genitalia; the nature of the hypertrophy is not yet certain but there is no doubt that some retrogression can occur and there is a possibility of ultimate damage to the testis There is also a risk of producing premature sexual maturity which at any rate may prove undesirable.

For these reasons I consider it unjustifiable to employ this treatment in any case where part of the genital apparatus is normal in development Moreover my findings suggest that pregnyl is unlikely to produce descent of a unilateral retained testis or of bilateral retained testes with good genital development Where both testes are undescended and the genitalia are under-developed the effect of treatment is to produce hypertrophy approaching the normal and it is in this class of case that successes are likely to occur

It is difficult to believe the accuracy of reports of successes after a few injections and one wonders how many of the successes claimed for gonadotropic hormones in the treatment of imperfect descent of the testis were really obtained in cases of retraction of the testis.

I have seen no case of descent where hypertrophy did not also occur

SUMMARY

1 Twenty patients with imperfect descent of the testis have been treated with pregnyl.

2 Hypertrophy of the external genitalia has been obtained in 10 patients

3 Descent of the testes has been obtained in 6 patients (5 bilateral, 1 unilateral)

4. It is suggested that in view of complications treatment with gonadotropic hormones should be used only in bilateral cases with subnormal genital development

I am greatly *indebted to the surgeons of St Thomas's* Hospital for their kindness in referring these cases to me and especially to Mr C Max Page under whose direction this work has been performed

THE FOURTH OR APICAL ELECTROCARDIOGRAPHIC LEAD

WITH REPORTS OF THREE CASES OF CORONARY THROMBOSIS WITH ELECTROCARDIOGRAMS

By Edward T Freeman M.D B Sc F R C.P Irel

PHYSICIAN TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN; VISITING CONSULTING PHYSICIAN ROYAL NATIONAL HOSPITAL FOR CONSUMPTION NEWCASTLE

In 1932 *papers by Wolferth and Wood and other* authors[1 2 3 4 5 6 7 8] began to appear in America dealing with a series of electrocardiographic leads which they called chest leads The first of these anterior chest to posterior chest was obtained by using the right-arm electrode on the front of the chest wall and the left-arm electrode behind To this lead IV they soon added leads V and VI In lead V the right-arm electrode remained on the chest and the left-arm electrode was shifted to the left foot; in lead VI the right-arm electrode is employed over the scapula whilst the left-arm electrode remained on the left foot This last gave a stunted tracing not unlike lead III which did not prove of definite clinical value In leads IV and V the tracing is essentially the same as it was soon found that, so long as it was sufficiently far from the heart the position of the indifferent electrode did not matter For convenience the posterior chest position of this electrode has been abandoned and thus by lead IV is now usually meant a tracing taken from the anterior chest wall to the left leg using the right arm electrode on the chest wall and the left-arm electrode on the left foot The position of the chest lead is of paramount importance The fourth interspace is now generally adopted as that position is over the ventricles in practically all chests and is more reliable than the fifth interspace with the patient recumbent The tracing gives a very slight P which is usually inverted a large Q and usually an inverted T (Fig 1) It is like an exaggerated inverted lead I

As these chest leads are being used in conjunction with the standard *leads it has been suggested* by Roth (1935) that the right arm electrode should be kept on the right arm and the left arm electrode used for the apical lead In this way a tracing distinctly analogous to the standard leads will be obtained showing the exaggerated complexes of the new leads without the inversion But the leads employed by the pioneers have had a long start and are now not likely to be displaced especially since they have been the subjects of much study and many papers published in America, chiefly in connexion with coronary sclerosis and thrombosis

The first papers were too critical of the older leads and too favourable to the new ones but gradually a more judicious view has prevailed and the precordial lead now seems certain to amplify *but not to suppress* standard electrocardiography The present view may be summarised as stating that in anterior lesions the large Q wave disappears and the R–T interval becomes depressed In the course of *some days* T_4 *becomes* upright but the Q_4 remains absent permanently This gives a very striking tracing as Q_4 of considerable size is present in all normal hearts and its absence leaps to the eye The only other condition in which Q_4 is commonly absent is in bundle branch block In the posterior lesions the findings are less definite There is an early elevation of the R–T interval which disappears in a few days leaving sometimes a pronounced inversion of T_4

CASE 1 —A doctor, aged 56, consulted Mr Seton Pringle about an acute abdominal pain He stated that he had had epigastric pain for some weeks and had been under treatment for a duodenal ulcer While in bed, taking light diet and alkalis, he had been much better, but the pain returned when he began to move about again He now felt he had appendicitis I saw him next day as the symptoms did not suggest an acute abdomen to Mr Pringle His pulse was normal and his heart sounds clear, there was no murmur The blood pressure was 136/90 mm Hg

He had a severe pain in the epigastrium, which was tender but not rigid, the pain passed through to the back but did not radiate to the arms On close questioning he admitted urgent dyspnœa for some weeks when going upstairs I suspected a coronary thrombosis, and when the patient was fit to move had an electrocardiogram taken It showed a very marked inversion of T_1 He was informed of the diagnosis and advised accordingly

Nearly two years later I was called urgently to the same patient whom I found in very extreme pain, again referred to the epigastrium He told me that his duodenum must have perforated During the interval he had had constant dyspnœa relieved by trinitrin I took an electrocardiogram on the spot (Fig 2) There was again T_1 inverted and a nodal rhythm Lead IV was very typical showing absence of Q and upright T His pulse was 100 and blood pressure 120/90 mm Hg He was given a large dose of morphine and dozed throughout the day with intervals of pain At 9 P M he suddenly began to wheeze and to cough, a short explosive effort with very rapid respiration and cyanosis The sputum which came up freely was pink froth This was relieved by morphine gr 1/3 with atropine gr 1/25 Next morning he was cold and cyanosed His features were pinched He had now pain in the left arm for the first time Dr Henry Moore saw him with me at 1 30 P M when he was more collapsed with systolic blood pressure under 100 That evening at 7 he had a further attack of left ventricular failure He died suffocated in my presence within five minutes of the attack's commencing with frothy pink mucus pouring from his mouth

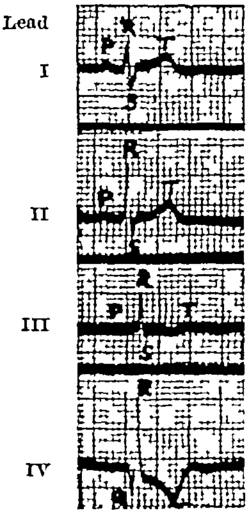

FIG 1.—Normal In lead IV prominent Q and inverted T

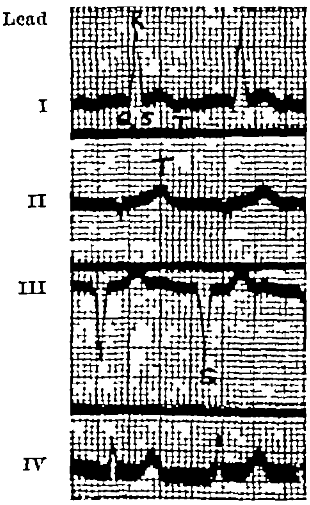

FIG 2 (Case 1)—Absence of P waves Splintering of Q R S complex inverted T_1 upright T_3 In lead IV absent Q and upright T

CASE 2 —A doctor, aged 79, was seen at his house in the country with Mr T J D Lane He had severe precordial pain of a squeezing type which radiated down his left arm For the past couple of weeks this pain had forced him to sit on the side of his bed for hours at night but he had continued his practice all day He admitted angina of effort for a few months An electrocardiogram taken on the spot showed low voltage complexes with T_1 inverted and lead IV of the typical coronary type (Fig 3) He was removed to a nursing home in Dublin where in spite of large doses of morphia the pain continued for two days He vomited a great deal On the fifth day his feet began to get cold, blood-stained blobs appeared on the skin Next day he was a little better and showed gradual improvement for five days further The urgency of the dyspnœa lessened, and he was able to spend all night asleep On the eleventh day, when apparently better than ever previously, he expired instantaneously while sitting up talking in bed

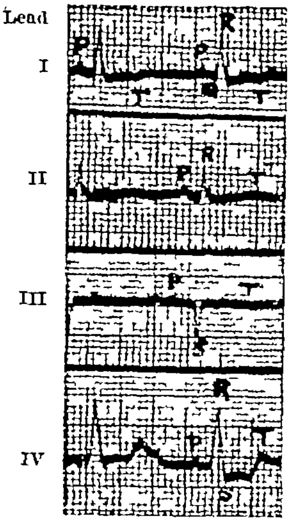

FIG 3 (Case 2)—T_1 almost iso-electric, inverted T_2, and T_3 iso-electric In lead IV absent Q depressed ST interval and upright T

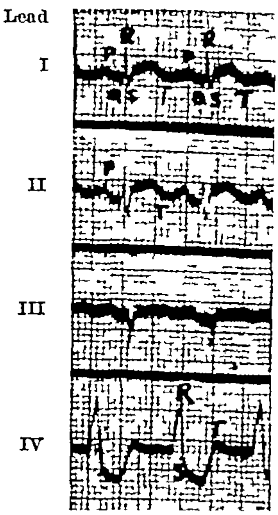

FIG 4 (Case 3)—Coved ST interval in leads I and II In lead IV absent Q depressed ST interval and upright T

CASE 3 —A farmer aged 39 A very strong robust man was, on Sept 20th, 1936, referred by Dr W F Foley of Tullow He had had severe pain for two days, radiating down both arms The pain was constricting and crushing in type and was located in the epigastrium rather than in the precordia The temperature was 100 6° F pulse rate 120 Gallop rhythm was present White cell count 17,800 He had been seen by Mr James Owens, who had excluded an upper abdominal lesion An electrocardiogram showed a coved R–T interval in leads I and II, and an absent Q and upright T in lead IV (Fig 4) He required very large doses of morphia, averaging one and a half grains per diem for five days The temperature ranged from 99° to 101° F for this period, gradually reaching normal The patient had drenching sweats during these days He has since progressed favourably For reasons other than medical it was necessary to allow him to return home by ambulance after three weeks He is now doing a little supervising and has had a couple of slight attacks of pain on exertion

SUMMARY

In these three cases the standard leads show typical abnormalities, which are much more marked in Case 3 than in the other two Lead IV shows pronounced changes in all the tracings This is very evident in Case 2, in which the alterations in the standard leads are not striking

THE FOUR LEAD ELECTROCARDIOGRAM IN CORONARY DISEASE

BY A WILLCOX, M.B Camb M R C P Lond.
MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL AND
J L LOVIBOND M B Camb M R C.P Lond.
CLINICAL ASSISTANT IN THE CARDIOGRAPHIC DEPARTMENT MIDDLESEX HOSPITAL

(*From the Cardiographic Department Middlesex Hospital London*)

WHEN the heart current is recorded by means of an electrocardiograph the form of the electrical curve obtained may be altered by varying the position of the electrodes on the body surface The three standard leads for the clinical electrocardiogram were introduced in 1902 by Einthoven who applied electrodes to the two arms and the left leg and connected them in pairs to the string galvanometer Until recently our knowledge of the normal and pathological electrocardiogram in the human subject has appertained almost entirely to these three conventional limb leads.

The clinical value of leads attached to the chest has only been appreciated during the last five years

In 1887 Waller the first to obtain electrical records of the human heart applied electrodes to the chest the limbs and the mouth and in 1909 Lewis employed chest leads in investigating auricular fibrillation It was not until 1932 that Wolferth and Wood, following their electrocardiographic study of experimental coronary occlusion (1933) advocated the use of an antero posterior chest lead in addition to the three limb leads, in the diagnosis of coronary occlusion in man Since this date experience of direct chest leads has been extended mainly in America and in 1936 Graybiel and White in a review of the present position concluded that the antero posterior chest lead had a definite value, especially in the localisation of cardiac infarction

The object of this communication is to report the changes observed in the antero posterior chest lead (lead IV) in a series of 102 consecutive cases of angina pectoris including 40 with coronary thrombosis and to evaluate the advantages of the four lead over the conventional three lead electrocardiogram

TECHNIQUE

Of the various chest leads employed one in particular called lead IV has proved most informative Wolferth and Wood applied the right arm electrode to the front of the chest over the apex beat and the left-arm electrode to the back of the chest between the angle of the left scapula and the spinal column following their practice adopted in experimental direct chest leads This procedure has been adopted by other American cardiologists [3, 6, 7, 10, 11, 14, 16, 17] The normal lead IV thus obtained is comparable with a standard lead in which all the deflections are inverted or in other words with a standard lead taken with the electrodes reversed (Fig 1c) It seems undesirable to introduce a new lead in which accepted criteria of normality are inapplicable when by a simple reversal of the electrodes it can be made to conform to conventional standards We have therefore applied the left-arm electrode anteriorly and the right-arm electrode posteriorly a practice already followed by Jervell (1935) and others [1, 13, 16, 20] and one which we hope will be generally adopted

The electrodes used in this investigation have been rectangular strips of German silver measuring 2½ in by 1¼ in supplied by the Cambridge Instrument Co and for a contact medium the Electrode Jelly of the same firm The left-arm electrode is applied over the apex beat or if this cannot be localised over the fourth intercostal space just to the left of the sternum and the right-arm electrode to the posterior chest wall, between the left scapular angle and the spine they are fixed in position by adhesive strapping

The position of the anterior electrode is the most important factor in determining the form of the electrocardiogram [3, 14] and it must be kept between the left sternal border and the cardiac apex The position of the posterior electrode may be varied considerably without appreciably affecting the electrocardiogram and a comparable curve is still obtained if this electrode is kept on the right arm, as preferred by Roth (1935) When patients were too ill to be moved in bed we have therefore used the apex right-arm lead of Roth in preference to the antero posterior chest lead

THE NORMAL LEAD IV

The form of lead IV in the healthy heart has been well established [5, 6, 13, 14, 17] and we have confirmed this in a series of 30 normal controls The following description applies to the antero posterior chest lead with the *left-arm* electrode placed *anteriorly* all deflections being of opposite sign compared with Wolferth and Wood s lead IV

The P wave is upright and of smaller amplitude than in the limb leads The RS complex is larger than in limb leads and is always diphasic, the initial deflection being positive and the positive and negative components approximately equal in amplitude The T wave is positive sharply peaked and large sometimes attaining an amplitude of 10 mm The iso-electric R–T segment is of short duration and may be elevated by 2 mm or depressed by 1 mm but not beyond these limits in health A positive U wave is frequently observed (Fig 1A) Using the apex right arm lead advocated by Roth the only significant difference is a larger P wave and a shift in the axis of the RS deflections (Fig 1B)

ABNORMALITIES IN LEAD IV

The same modifications are equally possible in lead IV as in limb leads namely widening and notching of the RS deflection, the presence of a Q wave deviation of the R–T segment from the zero level, flattening or inversion of the T wave and changes in rhythm A positive T wave exceeding 10 mm in amplitude called huge by Wolferth and Wood (1934) sometimes occurs and is to be regarded as pathological. Absence of the R wave or reduction of its amplitude to below 2 mm has been emphasised as evidence of myocardial disease and especially of anterior infarction by Levine and Levine* (1936) and has been observed in some but not all cases of anterior infarction by Jervell (1935) A small or absent R wave also occurs in the lævographic type of bundle branch block [11, 14] (left or Type I bundle branch block in the new terminology) Our results confirm that there is no characteristic shift in the axis of lead IV in association with left ventricular predominance [3, 6] Digitalis affects lead IV in the same way as it does the limb leads and we have observed a typical depression of R–T in several cases taking digitalis Strauss and Katz (1935) found that in normal subjects digitalis might deviate the R–T segment in either direction and flatten or reverse the T wave

A Technique used in this investigation with the left arm electrode on the cardiac apex right arm electrode at left scapula angle Note small P, RS biphasic with equal components, T upright

B Roth's method with left arm electrode on apex, right arm electrode on right arm Note larger P and shift in axis of RS

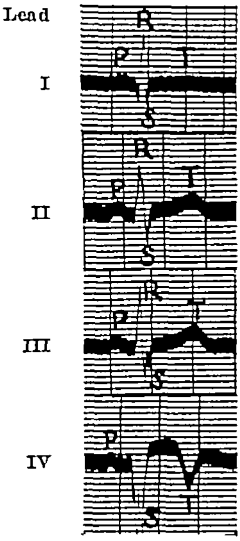

FIG 2 (Case 6)—Male aged 48 Angina of effort Absence of significant changes in limb leads with altered lead IV (R wave absent, S notched, R–T elevated, T inverted)

FIG 1 (*continued*) C Wolferth and Wood's method, with right arm electrode on apex, and left arm electrode on left scapula angle Note Q wave negative P and T waves

LEAD IV IN ANGINA PECTORIS

Four-lead electrocardiograms were obtained in 62 cases of angina of effort, 39 of which were men, 23 women. In 34 cases there were no significant changes in any of the four leads, in 11 both the limb leads and lead IV showed evidence of myocardial disease In 9 cases the limb leads were abnormal when lead IV was normal or showed only indefinite changes In 8 cases lead IV showed a significant abnormality when the limb leads were normal (see Table I and Fig 2)

TABLE I—*Angina of Effort* (62 Cases)

LEADS I II III	LEAD IV					
—	Normal	Normal T with abnormal R–S	R absent	T negative	T biphasic	T over 10 mm amplitude
Normal	6	3	1	1	0	1
Normal with left axis deviation	8	7	2	1	1	0
Normal with T_3 negative	6	4	0	0	1	0
T_1 negative	3	1	0	0	0	0
T_1 and T_2 negative	2	1	1	1	1	0
T_2 and T_3 negative	1	1	0	0	0	0
Abnormal Q R S (including 6 cases with bundle-branch lesion)	0	7	0	0	0	1

Thus in approximately 13 per cent of cases in this series lead IV provided evidence of myocardial disease which the three lead electrocardiogram failed to show In two instances in which this occurred there was a steeply inverted T wave in lead IV Both patients concerned (Cases 6 and 28) gave a history of previous attacks of severe and prolonged pain, suggestive of coronary occlusion These are of interest, since Edeiken, Wolferth, and Wood (1936), in a recent paper, have stressed the importance of a reversed T wave in lead IV, when it appears as the sole abnormality in the adult electrocardiogram They consider it highly suggestive of coronary disease, an inference which is supported by these cases, but on which some doubt had previously been cast by Levine and Levine (1936)

LEAD IV IN ACUTE CORONARY OCCLUSION

Four-lead electrocardiograms were obtained from 40 patients during or shortly after typical attacks of coronary thrombosis, and in 24 cases serial records were taken Of the patients 8 died, and in 5 necropsies were performed There were T_1 type electrocardiograms in 20 cases, T_3 type in 15, and atypical curves in 5 (see Table II)

T_1 type of electrocardiogram—Lead IV was abnormal in all 20 cases, and in 14 of them the abnormality was most evident in lead IV Serial records showed that at particular stages lead IV alone might be abnormal Thus in 7 cases at an early stage, and in 4 cases at a late stage, the only significant electrocardiographic changes were in lead IV (see Table II) In the T_1 type of curve, lead IV exhibits the same changes as lead I,[8 13 16 26] but often in an exaggerated form (Figs 3 and 4) Thus the R–T segment is elevated and the T wave inverted Often the R wave is small (2 mm or less in amplitude) or absent,[8 11 16 26] and this abnormality may be more persistent than T wave changes It

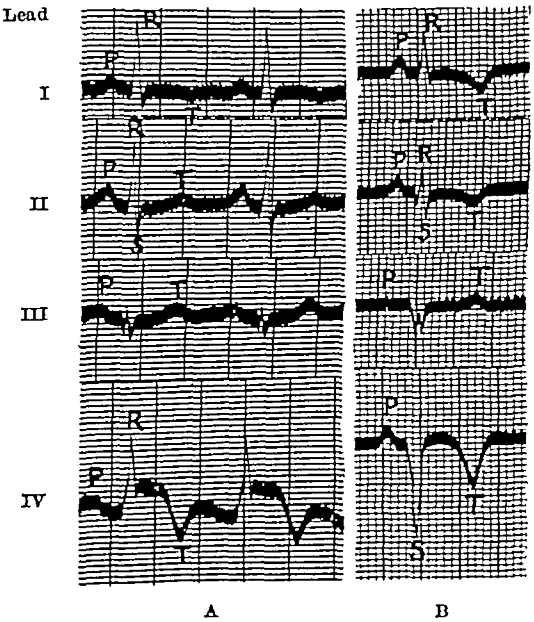

FIG 3.—Value of lead IV in early diagnosis of coronary thrombosis (T_1 type)

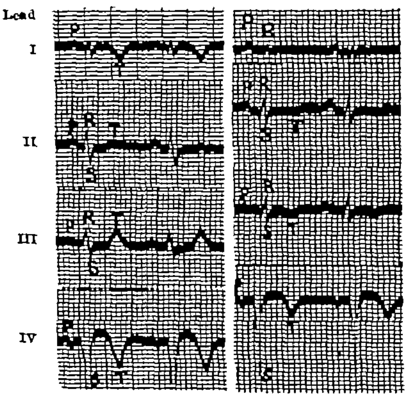
Case 81—Male aged 60 Acute coronary occlusion on August 29th Note diagnostic changes appearing earlier in lead IV

A Sept. 2nd limb leads slight inversion of T_1 only Lead IV characteristic elevation of R–T and inversion of T

B Oct 14th leads I and II T inverted Lead IV absent R, slight R–T elevation, T steeply inverted



A B

FIG 4—Value of lead IV in late diagnosis of coronary thrombosis (T type)
Case 68 —Male aged 61 Acute coronary occlusion on Oct. 12th 1935 Note changes persisting later in lead IV than in limb leads

A. Oct 17th All leads characteristic.
B July 29th 1936 changes in limb leads now indefinite Lead IV still abnormal (R absent R–T elevated, T inverted)

has occurred in 12 of our cases in 5 of which it was present at a late stage In 2 cases huge inverted T waves were seen The characteristic alterations of the R–T segment and T waves may occur sooner and last longer in lead IV than in standard leads

These changes are well illustrated by the following patient —

Case 81 a man aged 60 who was admitted to hospital four days after a typical attack of acute coronary occlusion

TABLE II*—*Acute Coronary Occlusion* (40 Cases)

—	T_1 type.	T_2 type	Anomalous.
Total cases	20	15	5
Lead IV normal	0	5	1
Lead IV abnormal	0	10	4
Lead IV abnormal with normal leads I II III	8	0	0
Changes more pronounced in leads I II III	4	15	3
Changes more pronounced in lead IV	14	0	0
Changes equal in all four lead	10	5	3

* Serial electrocardiograms were taken in 21 of these cases so that in some instances several records from one patient are included in the Table.

The electrocardiogram then showed obvious elevation of the R–T segment and inversion of T in the chest lead but no characteristic alteration of the limb leads (Fig 3A) Diagnostic changes did not appear in lead I until 3 days later In serial records extending over 7 weeks R–T elevation persisted in lead IV but disappeared in lead I after 5 days the T wave remained inverted in both leads but more deeply in lead IV (Fig 3B) The R wave in lead IV was absent after the 5th day of observation

In another patient (Case 68) a man aged 61 lead IV 23 weeks after acute coronary occlusion showed absence of the R wave elevation of the R–T segment and inversion of T, when the limb leads were not significantly altered (Fig 4)

T_2 type of electrocardiogram.—Lead IV was abnormal in 10 of the 15 cases but in none were the changes more evident in lead IV and often they were less evident than in standard leads (Figs 5 and 6) (see Table II) When lead IV was modified, it resembled lead I showing a depression of the R–T segment and an upright T wave In 3 cases huge upright T waves were seen (Fig 7) Occasionally lead IV showed an elevation of the R–T segment with a negative T wave, the significance of which is discussed later

Anomalous curves—In one patient (Case 101) the standard leads showed R–T depression in leads I and II and R–T elevation in lead III with upright T waves lead IV showed absence of R waves with elevation of R–T The post mortem findings are given in Table III In another (Case 102) the standard leads showed R–T elevation in leads II and III with inversion of T in all leads lead IV was normal. In 3 cases the standard leads revealed lævographic bundle branch block in these lead IV presented a small R wave and abnormal ventricular complexes closely resembling those in lead III but of greater amplitude

LOCALISATION OF CARDIAC INFARCTION

In 1928 Parkinson and Bedford showed that electrocardiograms from cases of acute coronary occlusion conformed to two main types and in 1929 Barnes and Whitten correlated these two electrocardiographic patterns with the site of the cardiac infarct, the T_1 type of curve corresponding to anterior infarction and the T_2 type to posterior infarction of the left ventricle These observations relate to standard three lead electrocardiograms More recently the use of various chest leads in the localisation of infarcts has been investigated especially by Wolferth and Wood[23 24 25 26] who recommend three

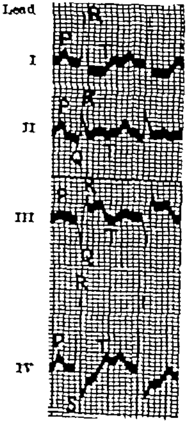


FIG 5 — R–T depression in lead IV
Case 100 —Male aged 62 Acute coronary occlusion on August 31st Electrocardiogram on same date showing limb leads with characteristic T type changes and R–T depression

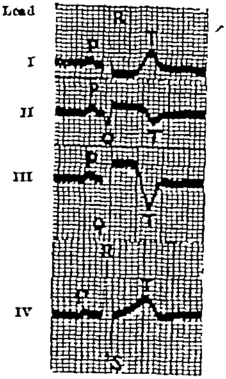

FIG 6.—Coronary thrombosis (T type) with lead IV unaltered
Case 91 —Female aged 66 Acute coronary occlusion on May 6th Electrocardiogram on May th showing typical appearance of limb leads with lead IV normal

chest leads (leads IV, V, VI), but the value of leads V and VI seems doubtful. Abramson and Weinstein[1 20] have employed chest leads in experimental coronary occlusion, and various clinical investigations relative to localisation of the infarct by chest leads have also been reported[8 11]

Acute anterior infarction—The standard leads show elevation of R–T_1 and depression of R–T_3, followed by an inversion of T_1 and often of T_2 Lead IV usually shows an elevation of R–T and inversion of T, in addition absence or diminished amplitude of the R wave is common

Acute posterior infarction—There is usually elevation of R–T_3, and depression of R–T_1, followed by inversion of T_3 and often of T_2 A large Q wave in lead III is commonly found Lead IV may show little change in posterior infarction, but if altered, there is a depression of R–T and a high positive T wave

Acute anterior and posterior infarction—When acute infarction involves both the anterior and posterior surfaces of the heart, Wolferth and Wood have found that the R–T segment is elevated in all limb leads, the maximum elevation being in lead II, in lead IV the R–T segment is also elevated—i.e., elevated with left arm electrode anterior as in our observations but depressed with right-arm electrode anterior There may be a large Q_3 suggesting posterior infarction, combined with an absence of R_4 suggestive of an anterior infarction

Other changes—Jervell attributes elevation of R–T_4 and inversion of T_4 to infarction involving the apex, and when this occurs in association with the T_3 type of curve it is explained by a posterior infarct encroaching on the apical region Huge T waves in lead IV, over 10 mm in amplitude, and either positive or negative, suggest localised apical infarction[25]

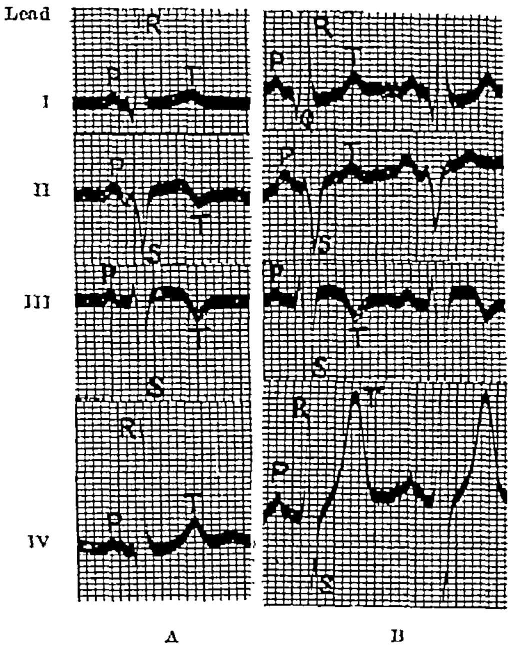

FIG 7—Huge T waves in lead IV
Case 99—Male aged 69 Acute coronary occlusion on August 1st

A August 12th Limb leads typical of T_3 type coronary thrombosis No significant change in lead IV
B Sept 5th T_3 inversion and R–T_3 elevation persist Lead IV with huge positive T (21 mm)

Post mortem evidence—Of the 6 cases that came to post mortem, 3 (Cases 87, 88, 94) showed posterior infarction (Table III), the electrocardiographic diagnosis of these had been made correctly in life by means of the limb leads, which were of the T_3 type In two lead IV was normal (see Fig 6), in the third (Case 87, Table III) the R wave was absent in lead IV, with slight elevation of the R–T interval This suggested myocardial disease possibly due to a previous anterior infarct and in fact, the necropsy revealed narrowing of the left coronary artery at its origin with patchy fibrosis of the anterior wall of the left ventricle In the remaining three cases lead IV was of more definite value The first (Case 10) was a man with syphilitic aortitis The only abnormality in the electrocardiogram was a positive T wave in lead IV of over 10 mm amplitude This suggested a localised apical infarct, which was subsequently confirmed The second (Case 82) showed the T_1 type of curve in the limb leads, with very pronounced R–T elevation, and in lead IV a negative T and absent R wave Anterior infarction was diagnosed, and an anterior and apical infarct was found post mortem The last (Case 101) showed depression of the R–T interval in leads I and II, with elevation in lead III In lead IV

TABLE III—LOCALISATION OF CARDIAC INFARCT (6 Post mortem cases)

Case	Age	Clinical diagnosis	Leads I II III	Lead IV	Electrocardiographic diagnosis of site of infarct	Necropsy
10	48	Syphilitic aortitis angina pectoris	Normal	Positive T wave exceeding 10 mm	Lead IV – apical	Syphilitic aortitis Left coronary orifice occluded right stenosed Apical infarct small apical cardiac aneurysm
87	50	Coronary thrombosis (intermittent bundle branch lesion)	(1) Bundle-branch lesion (lævographic) (2) R–T_3 elevated R–$T_{1,2}$ depressed	(1) Bundle branch lesion R small (2) R–T elevated T positive	Limb leads – posterior Lead IV – myocardial disease ? previous anterior infarct	Left coronary artery stenosed at origin circumflex branch occluded Right coronary occluded Posterior infarct Patchy fibrosis of left ventricle anterior surface
88	54	Coronary thrombosis	T_3 negative T_2 flat Q_3 large	Normal	Posterior	Left circumflex coronary artery occluded right coronary occluded Posterior and apical infarcts
94	66	"	R–$T_{2,3}$ elevated R–T_1 depressed $T_{2,3}$ negative	"	"	Left coronary artery patent right occluded Posterior infarct Ruptured left ventricle posteriorly
82	56		Low voltage Q R S R–$T_{1,2}$ elevated $T_{1,2}$ negative	Marked elevation of S–T R absent T negative	Anterior	Left coronary anterior descending branch occluded right coronary stenosed but patent Anterior and apical infarcts
101	63	"	R–T_1 depressed R–T_3 elevated	R absent R–T elevated	Limb leads – posterior Lead IV – anterior	Left and right coronary arteries occluded Antero posterior infarct of apex

the R wave was absent and the R–T interval elevated. These changes pointed to antero-posterior infarction which was confirmed post mortem.

Comment.—This is too small a series from which to draw conclusions but, when considered with the literature on the subject, it does indicate that the four-lead electrocardiogram is helpful in the diagnosis of anterior and antero-posterior infarction.

SUMMARY AND CONCLUSIONS

Lead IV is the name given to the antero-posterior chest lead, and its value lies in the diagnosis of coronary disease.

By means of the four-lead electrocardiogram we have investigated 102 consecutive cases of cardiac pain, using a technique which differs from that originally described by Wolferth and Wood. The chest leads have been reversed—i.e., the left-arm electrode in the anterior position—giving a lead IV comparable with the standard limb leads I, II, and III. We hope that this modification will come into general use.

In 8 out of 62 cases of angina of effort lead IV provided evidence of myocardial disease not given by the three-lead electrocardiogram. We have confirmed the value of lead IV particularly in the diagnosis of left coronary artery occlusion.† Characteristic changes may appear earlier or last longer in this lead; they resemble those in lead I. The four-lead electrocardiogram is useful also in the localisation of cardiac infarction, particularly in combined acute left and right coronary artery occlusion. This is substantiated by our post-mortem material.

We recommend the routine use of the four-lead electrocardiogram in the investigation of every case of cardiac pain.

We are indebted to Dr G. E. S. Ward and Dr D. Evan Bedford, under whose direction this work has been carried out; to the other physicians on the staff of the Middlesex Hospital for permission to use certain cases under their care; and to Prof. James McIntosh for permission to analyse our pathological material. We also wish to express our thanks to Mr E. Bridger, cardiographic technician, for his helpful coöperation throughout.

DEFENSIVE ROLE OF BILIRUBINÆMIA IN PNEUMOCOCCAL INFECTION

By Najib Farah, M.D.
FORMERLY INSTRUCTOR IN THE AMERICAN SCHOOL OF MEDICINE, BEIRUT

The discovery of pneumococci in cultures from the blood of a patient with long-standing subacute rheumatism (Najib-Farah 1933) led me to study the part played by the pneumococcus in rheumatic infections. It occurred to me that the defence of the body against this organism might perhaps be related to the solubility of pneumococci in bile, which is the basis of Neufeld's method of distinguishing pneumococci from streptococci. With this in mind I examined the blood of 17 patients with acute rheumatism and found that in all of them it showed abnormally large quantities of bilirubin. The values obtained ranged from 0·8 to 2·0 units van den Bergh (4–10 mg. bilirubin per litre of blood serum), whereas the normal is usually given as 0·2 to 0·8 unit (or 2–4 mg.). This fits in with the observation that hyperbilirubinæmia is found in infective diseases (Gradwohl 1935, Fellinger and Pfleger 1936) even when the liver is not apparently affected. But I have reason to think that the increase of bilirubin in the blood is not, as has been assumed, evidence of impaired function of the liver but forms part of a protective mechanism designed to overcome infection.

EXPERIMENTS

My first step was to test rabbit serum for bilirubin and I found that it contained none—which may explain why it is such an excellent medium for cultivating the pneumococcus. From this I went on to test the inhibitory effect of bilirubin on the growth of pneumococci. A series of seven tubes of tyndallised rabbit serum were prepared containing amounts of bilirubin (Merck) ranging upwards from 2 to 8 mg. per litre. (The bilirubin was free from bile salts.) For my test I chose an 18 hours culture of bile-soluble type III pneumococci sufficiently virulent to kill a mouse within 20 hours in a dose of 0·1 c.cm. The seven tubes were numbered 2 to 8 according to their content of bilirubin (2 mg. per litre of rabbit serum, &c.) and to each of them a drop of the pneumococcus culture was added. After 18 hours in an incubator at 37° C. they were again examined, and the findings were as follows:—

Tubes 2 and 3.—Organisms growing fairly well (less so in No. 3) though never abundant. Morphological characters less distinct in No. 3 than in No. 2.

Tubes 4 and 5.—Under the microscope the organisms showed here and there signs of agglutination (Fig. 1) and the beginnings of disintegration (Fig. 2).

Tubes 6 and 7.—All clearly showed bacteriolysis and there were capsular structures or frames of varying length which had lost their contents (Fig. 3).

Tube 8.—Complete lysis of the pneumococci, including their capsules. No growth at all had taken place.

This partial or total solubility of pneumococci in bilirubin has not, I believe, been previously described.

In my second experiment the same culture of pneumococci was added to normal human serum (heated and unheated) and to serum (heated and unheated) from patients with acute rheumatism whose serum bilirubin values ranged from 4 to 10 mg. per litre. I found that the pneumococci grew satisfactorily in the normal serum, though never abundantly as in rabbit serum, but were agglutinated and began to disintegrate in patients' serum containing 4–5 mg of bilirubin per litre The capsular structures were partly denuded of cocci by serum containing 6–7 mg (Fig 4), while complete lysis occurred at 8 mg per litre

My third experiment was to repeat the tests with normal human serum to which bilirubin had been added, using (*a*) mouse virulent streptococci, hæmolytic and non hæmolytic, (*b*) avirulent capsulated type II pneumococci obtained from pneumonic sputum, and (*c*) a mixture of the above virulent type III pneumococci and virulent streptococci In the series of tubes used for avirulent pneumococci the bilirubin content ranged up to 10 grammes per litre of serum The results were as follows —

Streptococcus —Growth normal in tubes containing up to 8 mg of bilirubin per litre No disintegration or lysis observed Agglutination occasionally noted

Avirulent pneumococcus —Growth normal and no signs of disintegration or lysis, even at a concentration of 10 g per litre (Fig 5) This organism was insoluble in bile Agglutination occasionally noted

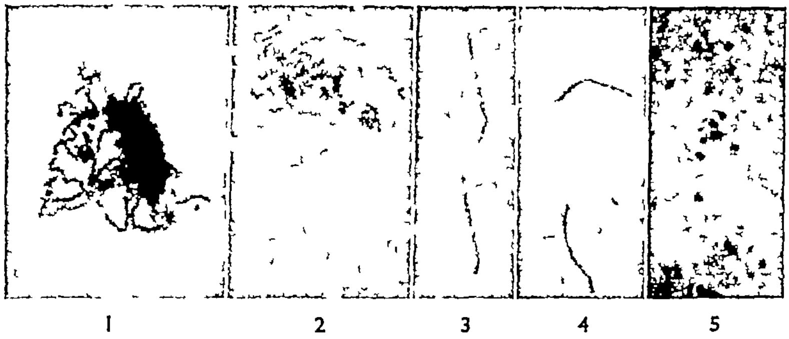

FIG 1 —Agglutination of pneumococci in rabbit serum containing 4 mg of bilirubin per litre

FIG 2 —Disintegration of pneumococci in rabbit serum containing 5 mg of bilirubin per litre

FIG 3 —Pneumococcus culture in rabbit serum containing 7 mg of bilirubin per litre The capsular structure remains but the contents have mostly disappeared

FIG 4 —Pneumococcus culture in human serum containing 6–7 mg of bilirubin per litre (1 3 units van den Bergh) The capsular structure is partially denuded of cocci

FIG 5.—Culture of avirulent pneumococcus in human serum containing 10 g of bilirubin per litre Normal growth No signs of disintegration or lysis

Streptococcus and virulent pneumococcus —Disintegration and lysis of pneumococcus Free growth of streptococcus

Several similar experiments were conducted with various pneumococci of types I, II, and III in rabbit serum Absence of virulence goes with insolubility in bilirubin, as it does with insolubility in bile salts, while moderate or feeble virulence is associated with insolubility or partial solubility It should be recognised however that the solubility (like the virulence) of a culture is liable to vary from time to time

POSSIBLE BEARING ON RHEUMATIC INFECTIONS

I have already given reasons (Najib Farah 1934) for thinking the pneumococcus capable of producing an illness indistinguishable from acute or subacute rheumatism.

Not long ago I saw a boy of 11 with severe sore throat, and succeeded in obtaining both from the blood and the throat a pneumococcus (Type I), which killed a mouse in 28 hours On the first day of the illness there was a bilirubinæmia of 1 2 units (van den Bergh), and from the second to the fifth day it ranged from 1 5 to 2 0 units The symptoms then abated, and the bilirubinæmia fell to 1 35 units, but on the eleventh day the patient developed a characteristic attack of acute rheumatism, and the bilirubinæmia rose to 1 60 units

My own interpretation of these observations is that in the first stage of infection bilirubin is mobilised in the blood to destroy the pneumococcus This leads to the disintegration of the organism with liberation of toxic substance which may be sufficient, after a latent interval, to give rise to the allergic reaction which we recognise as rheumatism Under these conditions, to catch the pneumococcus in the blood, one should search for it as early as possible during the initial sore throat of the disease, for cultures are apt to be negative in the established phase of the rheumatic manifestations

SUMMARY

(1) Seventeen patients suffering from acute or subacute rheumatism showed hyperbilirubinæmia (2) Test showed that rabbit serum does not contain bilirubin (3) Experiment showed that the growth of virulent pneumococci is inhibited by addition of bilirubin to the culture The organisms undergo agglutination and disintegration (partial and complete lysis), the capsules being denuded of their contents The same results were noted in serum of rheumatic patients containing bilirubin from 0 8–2 units (van den Bergh) (4) Some varieties of pneumococcus are agglutinable and soluble in bilirubin solutions, while others are not Solubility varies with virulence (5) *It is suggested that bilirubinæmia* should be regarded not as a sign of hepatic damage but as a means of defence Bilirubin should be then considered as an agglutinin and a lysin in vivo (6) This hypothesis is consistent with the idea that pneumococcal infection may give rise, after a latent period, to acute or subacute rheumatism The germ should be searched for in the blood, particularly in the initial sore-throat phase of the disease

I would like to thank Mr P Karayannis, the chemist of the laboratory of Dr J Papadopoulo, for his valuable assistance in the experimental investigation, and also Dr Papadopoulo himself for his courtesy in allowing me free access to his laboratory, and for his previous collaboration

SWANSEA HOSPITAL SERVICE —The Swansea health committee's five years' programme includes a supplemental general hospital with a maternity block, and an expenditure of £15,000 to provide immediate accommodation for maternity cases The new general hospital is estimated to cost £240,000

ANEURYSM OF THE SINUS OF VALSALVA INVOLVING THE CORONARY ORIFICE

BY NORAH H SCHUSTER, M.B Vict
PATHOLOGIST TO THE ROYAL CHEST HOSPITAL, LONDON

IN 1840 Thurnam collected 22 cases of aneurysm of the sinus of Valsalva. In the succeeding years Smith was able to find records only of another 20 This is doubtless due to the feeling that they are sufficiently well known to make further enumeration unnecessary They are nevertheless not often seen in the ordinary way—e g 2 in 3000 post-mortems at the Middlesex Hospital—and the following specimen is unusual enough to warrant publication

Coronary artery aneurysms are nearly always in the first inch of the artery but apart from a case described by Ward there has never been one that included the orifice Neither are they syphilitic as a rule Packard and Wechsler did not ascribe any of their series to that infection Syphilis of the coronary arteries causes obliteration rather than dilatation—Moritz collected 8 cases Two exceptions have recently been published one by Vogelsang and one by Snyder and Hunter who describe a specimen with separate aneurysms of the sinus and coronary artery both syphilitic

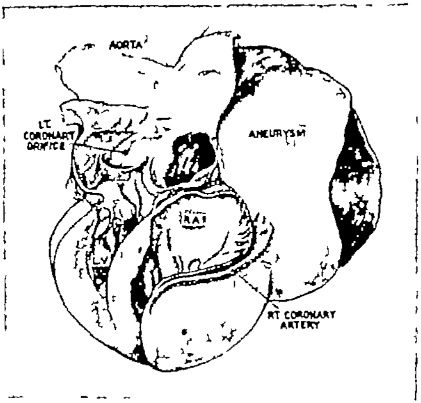
Aneurysms of the sinus of Valsalva on the other hand are usually syphilitic and really belong to the aortic group in fact in 20 per cent. of cases there are said to be aortic aneurysms as well (Smith) A rare type is probably congenital Goehring found 6 examples they were small membranous bulged into the heart and mostly perforated into one of the chambers

The patient a man aged 53 had been discharged from the army for chest trouble He attended Dr Barty King's out patients at the Royal Chest Hospital in 1918 with cough and hæmoptysis In 1920 pulsation on the left of the sternum was felt for the first time He then had clubbing of the fingers and slight cyanosis In 1921 an apical systolic murmur was first heard but the heart was not enlarged The patient also started having dyspnœa and angina pectoris and continued to have them during the succeeding years. The Wassermann reaction was found to be positive Later in the same year there is a note that the heart was enlarged to the left side and that there was a harsh systolic murmur over the precordia loudest in the pulmonary area During this year he had a stroke In 1922 the heart was still enlarged to the left only There was a systolic thrill at the apex, and the precordial ribs were pushed forward by a big powerful heart Breath sounds were almost absent at the right pulmonary base. X ray screening showed a rounded shadow on the left side of the heart but non pulsating The plate confirms it and suggests neoplasm" In 1923 he had pleuritic friction on the left side in front more angina and dyspnœa and the heart was enlarged in all directions Dr A W Stott made the following report: The electrocardiograph shows a flattened T wave in lead I and large upright T wave in leads II and III The R wave in lead II was splintered and there was a deep Q wave in lead III The P–R interval was normal In 1924 the X ray revealed pulsation and the differential diagnosis between neoplasm and aneurysm was again discussed The electrocardiograph was the same as in the previous year

Radiography—In 1925 Dr P Kerley made radiological examinations and gives the following account of the appearances during the next three years There was a pulsatile tumour attached to the left border of the heart shadow just below the left *main* branch of the pulmonary artery Oblique and lateral views showed no connexion between the tumour and the arch of the aorta. The œsophagus and trachea were not displaced ? cardiac aneurysm ? pericardial dermoid cyst ? encysted pericardial effusion. The size and position of the tumour were unusual for a cardiac aneurysm Later radiographs in 1926 and 1927 showed that the tumour had increased in size and was notching the anterior parts of the 3rd and 4th ribs This left no doubt as to the aneurysmal nature of the tumour The arch of the aorta and the pulmonary artery at no time showed X ray evidence of dilatation."

The only change in physical signs between 1925 and 1928 was the increasing size of the heart area and the appearance of a diastolic in addition to the systolic murmur at the apex In 1928 he died suddenly from perforation of the aneurysm into the left pleural cavity

Necropsy—On removal of the sternum a large aneurysm was exposed which covered the whole front of the heart except the apex, and was adherent to its upper half It extended on both sides beyond the borders of the heart especially to the left where it reached beyond the costochondrial junctions, and was firmly attached to the chest wall at the 3rd and 4th ribs Its upper limit was about 2 in above the aortic valve and it burrowed a little between the aorta and pulmonary artery The pericardial sac was obliterated; in places the adhesions were firm and in places they were separable with a thin layer of coagulated blood between the parietal and visceral pericardium



Posterolateral view of the heart The aneurysm has been pulled over to the right to show its size. L.V = left ventricle. R.A = right auricle.

Internally the aneurysm was in relation with the anterior and medial walls of the right ventricle and auricle and the upper anterior corner of the septum The pars membranacea was not involved Part of the internal wall was very hard from calcification and old coagulum; it compressed the right auriculoventricular opening and projected like a wedge into the right ventricle almost dividing it in two and considerably flattening the upper part of the chamber

The orifice of the aneurysm was in the right sinus of Valsalva. It was roughly oval and wide enough to admit half a crown and had a smooth hard rim It led straight into the sac which was large enough to take two fists and had a very rough atheromatous wall with patches of coagulum on it It was so easily torn by the removal of the sternum that the perforation was not identified, but as the left pleural cavity was full of blood there was no doubt of its existence

The distal portion of the right coronary artery was traced along the auriculoventricular groove as far as the aneurysm it then became incorporated in its wall and could be seen as a tortuous ridge running to the inside edge of the orifice of the sac There was no proper opening into the sac but the wall was very atheromatous just there, and a probe entered without difficulty The artery was patent and apparently healthy in the distal portion but not patent in the aneurysmal wall. There was no separate coronary orifice in the right sinus The left coronary artery had a few spots of atheroma and the orifice was slightly contracted The aorta showed syphilitic aortitis and a little pouching just above the aortic valve, there was little or no dilatation of the ascending arch Atheroma extended up the arch and up into the main vessels The left ventricle appeared to be healthy The right ventricle was moderately hypertrophied

The inclusion of the coronary orifice in the aneurysm made it difficult at first to be certain whether the dilatation had originated in the coronary artery or in the sinus of Valsalva, and it was only after the remains of the artery had been dissected that the diagnosis was established Ward recorded a similar aneurysm which he described as having "involved the coronary artery," but Packard and Wechsler, in an analysis of 31 cases of coronary artery aneurysms, regard Ward's as belonging to the sinus of Valsalva

These aneurysms give notoriously complicated physical signs, and they are rarely diagnosed during life In this case the early radiographic reports were misleading, as they persistently suggested neoplasm despite the clinical evidence in favour of aneurysm There was evidently a difference of opinion about the nature and interpretation of the pulsation Smith says that peculiar thrills and noises, especially rough to and-fro murmurs heard best in the pulmonary area, may be suggestive of a sinus aneurysm In this case the most striking features were the sudden onset of marked pulsation and severe dyspnœa with very little cyanosis

Snyder and Hunter discuss the effects of aneurysms bulging inwards and causing heart block by pressure on the bundle of His, or obstructing the auriculo-ventricular passages This aneurysm certainly obstructed the tricuspid valve, and Dr Barty King considers that the apical systolic and diastolic murmurs belonged to that valve He also remarks that the early harsh systolic murmur seemed to originate in the pulmonary artery and might have been due to pressure

The specimen described above was undoubtedly syphilitic, with a good deal of atheroma as well, in appearance it was just like an advanced saccular aneurysm of the arch of the aorta Its size was exceptional, most of the recorded cases having been about the size of a walnut, while some of them were mere pouches Sheldon described a large one in the right sinus which extended towards the right and burst externally, but he does not give the exact size or mention the right coronary orifice

I am much indebted to Dr Barty King for permission to use his notes, and for his interesting comments on the clinical aspects of the case

CLINICAL AND LABORATORY NOTES

CUTANEOUS MELANOMA

TWO CASES ALIVE THIRTY AND THIRTY EIGHT YEARS AFTER OPERATION

BY J HOGARTH PRINGLE, M B Edin, F R C S Eng
CONSULTING SURGEON TO THE GLASGOW ROYAL INFIRMARY

ABOUT thirty years ago I published a paper[1] describing what I believe was an original method that had not previously been carried out, or even suggested, for operating for melanoma of the skin The principles advocated were

(1) To surround the primary growth with an incision as far removed from it as judged to be necessary

(2) To run from the most convenient point in this generally elliptical or ovoid incision a second one along the normal course of the main lymphatic trunks as far as necessary to allow free removal of at least the nearest lymphatic glands

(3) To reflect the skin well back and to each side from these incisions and excise the tumour with the whole of the subcutaneous tissue exposed containing the lymphatic vessels, the deep fascia of the limb and the fascia propria of muscles exposed along with the lymphatic glands in one continuous strip

The melanomata have a curious tendency to affect the lymphatic vessels in their course between the primary growth and the nearest lymphatic glands and at a comparatively early stage of the disease, a feature which is only rarely seen in other types of malignant cutaneous growths and then in a much later stage The main object of the operation is to remove all subcutaneous tissue in which satellites of the primary tumour might be developing, along with all, or as many as possible, of the main lymphatic vessels passing from the tumour to the nearest glands, in addition to the tumour and the glands

THREE CASES

I only met with three instances of melanoma of the skin in the course of my active work.

CASE 1 —The first was an old man who came to my out-patient department when I was an assistant surgeon at the Glasgow Royal Infirmary He had a small non ulcerated pigmented tumour in the flexure of his right elbow joint, but in addition there was a large mass of glands adherent to the skin and contents of the right axilla and innumerable pigmented nodules varying in size from small shot to a pea, some adherent to the overlying skin, others free from it scattered over the inner and posterior aspects of the right upper arm all the way from the primary tumour to the axilla The condition was considered to be inoperable

CASE 2 —The second patient was a girl aged 17, who was admitted to my ward in the Glasgow Royal Infirmary on Nov 12th, 1898 Her own medical attendant wrote saying he believed she had a melanotic sarcoma of her left forearm Two years before admission she had observed a small growth in the skin of the left forearm It had gradually increased in size and recently rather more quickly She did not admit there had been any wart or mole at that site and no injury could be recalled There was a small nodulated hard tumour measuring 3 5 by 3 cm adherent to and infiltrating the skin at the flexure fold of the left elbow The whole had a brownish colour with deeper brown areas here and there and some bluish black ones It could be moved slightly from side to side but not in the axis of the limb It was situated about mid way between the two condyles of the humerus. The left axillary glands were enlarged but no further evidence of spread was evident The liver was not enlarged and the urine was normal. A coloured sketch was made of the limb and the tumour This is now in the Museum of the Royal College of Surgeons Edinburgh (No 0 (1) b 03)

---

[1] *Edinb med J* June 1908

On Nov 18th the tumour with a good area of apparently healthy skin was surrounded by an elliptical incision from the upper end of which a vertical incision along the inner bicipital groove was run up to the apex of the axilla and on to the thoracic wall (Fig 1) The margins of this long wound were dissected back to each side and the skin bearing the tumour with the whole extent of subcutaneous tissue exposed by the reflection of the skin along with the bicipital fascia a strip of subcutaneous tissue at least 2 in in width down to and including the fascia propria of the brachialis anticus muscle were removed along with the fat and glands of the axilla in one continuous strip The margins of the wound with some undercutting near the site of the tumour came together fairly well one relaxation suture was inserted at the gap left by the excision of skin The whole healed well but when the patient was allowed to use the arm a small area at the elbow broke down though it quickly healed and she went home on Dec 24th

The tumour proved to be a melanotic sarcoma and the axillary glands some of which were definitely pigmented were infected The tissues removed at operation owing to a misunderstanding were not preserved after micro scopic examination was made

The patient was seen at frequent intervals She had good use of the arm and remained in good health In 1902 she went to Canada and married and has had three children I have heard from her frequently during the interval; she always sent a good report of herself and of her arm There has never been any further evidence of the tumour; and I have often thought that pregnancy has a remarkable tendency to light up any potential malignant cells that may exist The patient has never been irradiated and has only had the single operation 38 years ago I have recently heard from her and received a photograph which pictures a handsome sonsie lady She writes: I keep real well and my weight is 200 pounds.

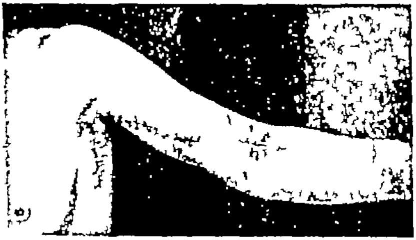

FIG 1 (Case 2) —Position and extent of incision for successful removal of a melanoma of the forearm in a girl aged 17

CASE 3 —The second patient for whom I operated is a man who at the age of 30 was admitted to the Glasgow Royal Infirmary on Oct 27th 1906, with a deep black nodule in the skin measuring 3 by 4 cm at the inner aspect of the left thigh just above the condyle The skin over it was very attenuated but not broken The tumour had developed during the previous two years from a small pigmented mole that had been present from his birth There was a large mass of glands visible in the left Scarpa s triangle which showed a brownish black coloration below the skin which was not adherent Enlarged glands were also palpable above the left Poupart ligament in the iliac fossa The liver was not enlarged and the urine was normal On his body were numerous small " de Morgan spots

On Nov 1st the tumour with the glands of left groin and those in the iliac fossa as far up as the bifurcation of the common iliac artery along with a broad strip of the subcutaneous tissue and the deep fascia of the thigh between the primary growth and the femoral glands, were excised in one strip as in the last patient (Fig 2) The wound healed asep tically The tumour proved to be a melanotic sarcoma the femoral and some of the lowest iliac glands were infected but the higher iliac glands were free of sarcoma cells.

A coloured sketch of this tumour was also made before the operation and is now in the Edinburgh Royal College of Surgeons Museum (No 5 (20) b 3) The specimen is in the Pathological Museum of the Royal Infirmary The patient was brought before a meeting of the Glasgow Royal Medico-Chirurgical Society on Feb 7th 1908 He is still well at the time of writing these notes thirty years after his operation He has never had any further treatment for the melanoma and has never been irradiated In 1923 however I removed a small pigmented mole from the inner side of his left thigh No recurrence has taken place at or in the scar or in the glands.

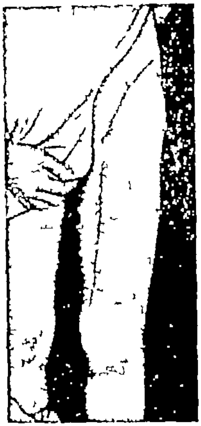

FIG 2 (Case 3) —Incision for successful removal of melanoma in lower part of left thigh

In my original paper I wrote: A radical extir pation of this disease will most certainly be ensured by excision of the tumour with a good zone of healthy skin around it and a somewhat larger zone of the underlying subcutaneous tissue and deep fascia along with a broad strip of subcutaneous fasciæ up to and including the nearest anatomical group of glands at least and all that is removed should be in one continuous strip The after history of these two patients—the only two on whom I have operated for melanoma—is good proof of the force of this contention

A CASE OF STREPTOCOCCAL SEPTICÆMIA TREATED WITH PRONTOSIL

By G L Robinson M B Camb

On Jan 1st 1937 a very thin boy [illegible] years old was admitted to the Royal Victoria Hospital Netley with slight cough and a five day swelling at the angle of jaw (right) The right tonsil was enlarged and inflamed.

On admission the temperature was 101 F the pulse-rate 136 and the respirations 30 Three days later on Jan 4th the temperature was swinging between 101 and 104 there was pain and slight swelling of the left wrist and the leucocyte count was 23 200 (87 per cent polymorphs) Antistreptococcal serum (20 c cm.) was given On Jan 6th the neck was incised and a little deep pus was evacuated, one tube was left in for drainage A hæmolytic streptococcus was grown from the pus, and during the next day or two there were further rises of temperature to 104° with rigors No obvious pus was seen on the dressings Antiscarlatinal serum (10 c cm) was given on Jan 8th and again on the 9th, when the tube was removed and the wound packed with eusol gauze At this time there was pain and slight swelling of left ankle, and a culture was taken from the blood On Jan 11th 20 c cm of antiscarlatinal serum was given No valvular murmurs heard Rhonchi in lungs Breath sounds harsh Temp, 98–103° with rigors, pulse rate, 104–140, respirations, 35

From Jan 12th to 14th there was pain in both ankles, the respiration rate was rising (to 60), and signs of broncho pneumonia appeared in the lower lobes A final injection of 20 c cm antiscarlatinal serum was given on Jan 13th

On Jan 11th a hæmolytic streptococcus was found in the blood culture Administration of Prontosil (Red) began on the 12th, and 7 5 c cm was given each night and morning by intramuscular injection (total 100 c cm = 2 5 grammes) From the 12th to the 29th the patient also received one tablet of Prontosil Album by mouth every six hours (total 70 tablets=21 g) In view of his small weight these quantities amount to double the average dose used in puerperal cases by Colebrook and Kenny (*Lancet*, 1936, 2 1319) On Jan 15th radiography of the chest disclosed no pus The flow of pus from the neck wound was increasing and there was œdema of scrotum On the 20th a pleuropericardial rub was noted but the temperature was steadying between 100° and 101° Pulse rate, 130, respirations, 40 A blood culture taken on this day proved sterile On Jan 26th the temperature fell to 97°, and it continued thereafter along normal lines The pulse rate fell to 100, and the respirations to 24 Only a soft pulmonary systolic murmur could be heard, the heart being dilated Albuminuria slight or absent Gauze packing in neck wound daily soaked with pus Cough ceased, but still signs of bilateral pneumonia and of dry pleurisy (left) By Jan. 31st the child was out of danger, and he has since made a steady recovery

The dates and results of the blood cultures in relation to the prontosil treatment are suggestive of cure by this drug, but since there were no signs of a valve lesion it remains possible that recovery would have taken place without its aid

These notes are published by kind permission of Colonel G F Rudkin D S O officer commanding the Royal Victoria Hospital Netley, Hants

SULPHÆMOGLOBINÆMIA FOLLOWING ANTISTREPTOCOCCAL CHEMOTHERAPY

By L D B Frost, M B Lond.

LATE HOUSE SURGEON ROYAL SALOP INFIRMARY SHREWSBURY

A girl aged 12 was admitted to the Royal Salop Infirmary on Jan 18th, 1937, with a history that four days previously she had been pricked by a penknife on the knee

She looked ill and was in much pain Her temperature was 101° F and her pulse rate 120 On the right knee there was a small scab lateral to the patella (? result of penknife injury) with swelling and redness medial to the patella The joint was tender and movements very, but not excruciatingly painful The liver and spleen were not palpable, and nothing abnormal was found in the urine

A diagnosis of suppurative arthritis was made and the joint accordingly opened A few drachms of seropurulent fluid were obtained (which on culture proved to be sterile) the joint was closed and a drainage tube inserted down to capsule Next day the temperature and pulse rate fell to normal, but there was still much pain in the joint It was decided to try Prontosil, and 5 c cm was given daily by injection for two days, with Proseptasine (p benzylaminobenzenesulphonamide) two tablets by mouth three times a day After the patient had had 10 c cm of prontosil and 12 tablets of proseptasine she was noticed to be cyanosed She was still in much pain but her temperature and pulse rate were not raised The urine on the previous evening had been pink in colour, but this was thought to be due to the excretion of prontosil in it, no further discoloration was noticed, and the bowels were well open with laxatives (magnesium sulphate was not given) The use of prontosil was discontinued, and oxygen was administered continuously with, however, no lasting effect The child died on the fourth day, the signs just before death being those of respiratory failure

Post mortem the striking points noticed were marked and early hypostases, darkness and fluidity of the blood, early fatty changes in the liver, and some staining of the intima of the first part of the aorta The lungs were normal and the heart revealed no congenital lesion The right knee joint contained about 3 drachms of frank pus in which many streptococci were demonstrated A spectroscopic examination of post-mortem blood showed the well marked absorption bands of sulphæmoglobin.

Colebrook and Kenny (1936a), in a series of 38 cases of puerperal infections treated with prontosil, records non fatal sulphæmoglobinæmia in three patient, in one of whom it developed after as little as 4 g had been taken They quote van den Bergh and Revers, who stated that, in a case of sulphæmoglobinæmia following the use of pyridium, the simultaneous administration of magnesium sulphate might have been a contributory factor Later Colebrook and Kenny (1936b) reported another series of 26 cases of puerperal infections treated with prontosil, in which there were no further instances of sulphæmoglobinæmia, incidently they withheld magnesium sulphate from these patients, the first series all having had it In the second series, also, they halved the dose of prontosil, in all but the very grave cases, but continued its use over a longer period

In the present case two possible causes of death spring to mind—namely, idiosyncrasy and overdose (A normal dose is an overdose to a “sensitive” patient) In Colebrook's series, as mentioned before, as little as 4 g caused sulphæmoglobinæmia, and this leads one to suppose that a small proportion of people have an idiosyncrasy to the drug—an idiosyncrasy that may even prove fatal In view of the recommended dosage I do not think an overdose, in the ordinary sense of the word, was given in the case I am recording

I am indebted to Mr A Simpson, under whose care the patient was admitted, for permission to publish this case

Donations for the Belfast Hospitals—A gift of £100,000 is to be distributed among Belfast hospitals and charitable institutions by Sir George Clark and Captain H D Clark, who are commemorating their parents, the late Sir George and Lady Frances Clark, in this way The Royal Victoria Hospital and the Children's Hospital will each receive £15,000

Victoria Infirmary, Glasgow—A steady increase in the work done at the Victoria Infirmary is described in the annual report The cost of maintenance is now over £85,000 per annum, and during the past year £6000 had to be drawn from capital During the year 1151 patients were treated in the paying patients' wing, and the governors are satisfied that this department is fulfilling a very useful purpose without being a burden on the general income

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON

AT a meeting of this society on Feb 22nd with Sir WILLIAM WILLCOX, the president in the chair a discussion took place on the

Ætiology and Diagnosis of Jaundice

Dr C E LAKIN introducing the subject spoke first of blackwater fever and described a fatal case In this disease hæmoglobin was liberated from the corpuscles so rapidly that the cells of the reticulo endothelial system were completely overwhelmed hæmoglobin appearing in the urine and the skin becoming deeply pigmented. This hæmolytic pigmentation sometimes followed the transfusion of incompatible blood if death was delayed a few days There was no sharp line of demarcation between the hæmolytic pigmentation of these conditions and that of so called hæmolytic jaundice, with excess of pre hepatic bilirubin Other examples were in pernicious anæmia acholuric jaundice malaria oroya fever poisoning by potassium chlorate sulphonal, or certain snake poisons and in some cases of septicæmia when it rendered the prognosis still more grave The next group was that of toxic or hepatogenous jaundice, with a retrograde change in the parenchymatous cells of the liver which could no longer transmit the usual hæmolytic products to the bile capillaries Except in acute yellow atrophy and the graver cases the changes in the skin and in the colour of the stools were only slight There was usually some enlargement of the spleen With widespread destruction the whole function of the liver was seriously affected and pyrexia persistent vomiting petechial and other hæmorrhages, delirium and coma often preceded death In the obstructive jaundice group the digestion and absorption of fat was so defective that the total fat might form 50 per cent. of the stools Constipation was the rule but there was sometimes diarrhœa, ascribed to fermentative changes The slow pulse often seen was attributed to the toxic action of bile salts on the sino auricular node.

In the differential diagnosis of jaundice a sudden onset in the healthy suggested obstruction of the common bile duct by a gall stone whereas a slow onset of increasing jaundice was associated with a new growth or pressure on the duct from without Jaundice immediately after attacks of violent paroxysmal pain usually meant the passage of a gall-stone along the cystic duct into the common bile duct A painless onset preceded by evidences of gastroduodenal catarrh suggested in a young adult catarrhal jaundice An initial loss of weight was seen in pancreatic disease and in malignant disease of the alimentary tract The occupation might afford a clue as in the use of such substances as carbon tetrachloride and trinitrotoluene Certain drugs might produce the symptom such as Atophan and Salvarsan In the general clinical examination attention should be paid to nutrition and the tonal condition of the abdominal wall. If the liver was passively congested or if there was hepatitis it would be tender on palpation Attention should be paid to the gall bladder the epigastrium the spleen the supraclavicular fossa for enlarged lymphatic glands, and the lung especially the right base In late stages of cirrhosis of the liver the first sound of the heart was noticeably defective in tone and the rhythm was often tic tac. A rectal examination should never be omitted in a doubtful case The urine was tested for bile pigment and bilirubin would be detected either by the iodine or the nitric acid tests Obstructive jaundice was characterised by putty like stools bile pigment and probably bile salts in the urine, and the jaundice was more likely to be intense than in the hæmolytic or toxic groups The blood gave an immediate direct van den Bergh reaction In the hæmolytic group the urine would not contain bile but urobilin was likely to be present sometimes in considerable amount The stools might be darker than normal Cases needed a complete blood count fragility tests and a determination of the mean corpuscular volume, a count of reticulocytes and blood platelets and the Wassermann test. In the toxic form the patient was often seriously ill and often feverish though the jaundice was not necessarily intense. Small quantities of bile might be found in the urine in addition to bilirubin In severe cases albumin and casts were always present because of the accompanying kidney damage

LABORATORY TESTS

Dr GEOFFREY HARRISON dealt with laboratory tests in jaundice Van den Bergh's method was accepted as the standard procedure for detecting bilirubin in the blood its main chemical value was to show hyperbilirubinæmia when the patient had a slight yellow tint and the condition could be detected before the onset of actual jaundice In established jaundice it showed the progressive changes in the concentration of the pigment in serum Estimations of bilirubin in the blood were as valuable in diseases of liver and biliary passages as those of blood urea in renal disease. Though direct van den Bergh reactions indicated mechanical obstruction he thought the test could not be properly interpreted until more was known of the physical chemistry of bilirubin and of the reaction He would like to cease reporting the direct test until that knowledge was available; he suggested that there was only one type of bilirubin though variations in other factors made it appear that there were two The usual chemical tests, such as the nitric acid and iodine ring tests were not sensitive enough A much better reaction which was very useful in clinical work was an application of Fouchet's test to a barium precipitate from urine It did not give positive reactions in health nor with pigments other than bilirubin The diazo test could also be applied to this precipitate and was also a sensitive method

Dealing next with stercobilin in fæces, Dr Harrison said that bilirubin was present in meconium, but after infancy except in gross diarrhœa it was said never to appear in the fæces Hence the stools should be tested for stercobilin and the colourless stercobilinogen not for bilirubin Describing the galactose test, he said that about 40 grammes of galactose was the maximum oral dose with which a liver whose cells were not damaged could deal and this dose seemed to be independent of sex age and body weight After this amount in health the peripheral capillary blood-sugar usually rose as much as after the same dose as glucose but this rise was presumably due mainly to glucose formed from liver glycogen not to galactose It was the amount of sugar in the urine which mattered blood sugar level and blood-sugar curves were of no assistance Phosphatases were enzymes which hydrolysed phosphate-esters to liberate inorganic phosphate and were widely distributed in tissues the greatest concentrations occurring in bone, kidney, intestinal mucosa, liver, and red cells Traces were present also in plasma or serum in health The plasma phosphatase was increased in active bone diseases and in obstructive jaundice, but an estimation was of only limited value in separating the obstructive group from the other types

TOXICOLOGY

The PRESIDENT said that the liver damage due to the use of "dope" in aeroplane work at the beginning of the late war was caused by tetrachlorethane It had been found that practically all the factory staff were slightly yellow, that they had morning vomiting, and some had ascites He had also seen during the war some fatal cases of trinitrotoluene and of atophan poisoning Many cases of toxic jaundice had occurred after using some of the new drugs, such as Luminal, and he had seen it follow the use of Plasmoquine, acriflavine, and Avertin Trichlorethane, largely used in dry cleaning, also produced jaundice, and atrophy of the liver sometimes followed the giving of carbon tetrachloride One of the main functions of the liver was the toxiphylactic, it protected the body by removing poisons from it, including those produced in internal metabolism In toxic jaundice the key to the situation was the liver cell Nature had been generous in that she provided fourteen times as many as were needed for ordinary requirements, hence the ability of some people to stand such large doses of alcohol as they were known to take Chloroform was a very rapid liver poison, and in phosphorus poisoning all the liver cells became swollen and were the subjects of fatty degeneration, they necrosed, the liver then shrank, and while this was proceeding the kidney cells became damaged, and acute yellow atrophy supervened Thus it was all one picture, it was a question of time and the intensity of the poison Dr Lakin had said that in toxic jaundice it was rare to see pale stools This was because of the swelling when the tension was increased and the bile ducts blocked by squeezing, but he had seen pale stools lasting three or four weeks in toxic jaundice The depth of the jaundice was not much guide as a means of differentiating the toxic from the obstructive type, but he considered that the van den Bergh reaction was good for the diagnosis of hæmolytic jaundice He agreed with Dr Harrison's remarks concerning the liver function tests The liver varied greatly in susceptibility to poisons, and old people were much more susceptible to them than were younger folk, especially with such drugs as atophan and the barbiturates

TROPICAL DISEASES

Dr P H MANSON BAHR said that the discovery of the cause of blackwater fever would shed more light on paroxysmal hæmoglobinuria and acholuric jaundice than any other means In blackwater fever the giving of quinine had much to do with the onset of the paroxysms, but since the advent of Atebrin, which killed the sub tertian parasite, it had practically ceased to exist in this country, though in London 10–20 cases yearly were once seen One of the means of curing the disease was by giving large quantities of fluid, one of his severe cases became maniacal, and managed to procure and drink a large quantity of beer, after that he began to recover The speaker was the first to point out ten years ago, the similarity of the renal condition in blackwater fever to that in incompatible blood transfusion, and it had been many times confirmed since Plasmoquine might cause methæmoglobinuria, and carbon tetrachloride might cause toxic jaundice, just as chloroform did, but it would be wrong to ban these valuable drugs on that account Dr Lakin had mentioned amœbic hepatitis and amœbic dysentery as causes of jaundice, but he himself had always held that amœbic abscess of the liver was not associated with the symptom jaundice Carotinæmia caused a great discoloration of the skin, and was very rife among residents in Nigeria, possibly because a large part of the diet there was fresh vegetables

---

SOCIETY OF MEDICAL OFFICERS OF HEALTH

AT a meeting of the Maternal and Child Welfare Group of this society held on Feb 19th, Dr AGNES NICOLL, the president, being in the chair, Dr PETER MCKINLAY read a paper on the

Economics of Child Welfare Work

He said that his subject really involved an attempt to equate child welfare activities with the improving health of the population at the ages concerned Before any assessment of expenditure and return could be made, it was essential to find where and to what extent child welfare activities had been operative

He proposed, therefore, to summarise the changes shown by vital statistics for the ages concerned and to discuss the effects of some of the relevant factors Both in Scotland and in England and Wales the infant mortality rate had shown no tendency to improve until the end of the last century, but since then had dropped from 150 to about 60 in England and Wales and in Scotland much less, from 120 to about 80 The differences in rates of improvement in the infant death rate from various causes and in different areas could hardly be studied before 1911 and so he had taken out figures relating to the five quinquennial periods since then Comparing the first and last of these periods the rate was found to have declined for all causes by 43 per cent, that due to convulsions falling most, congenital debility, tuberculosis, syphilis, diarrhœa, measles, and overlaying following next on the list in that order Deaths from premature birth showed negligible improvement, congenital malformations were half as much again as in pre war days and the mortality attributed to birth injury was exactly doubled The decline had been more noticeable among illegitimate than legitimate children, and only in respect of diarrhœa did this not hold true The contrast was greatest for birth injury which had not increased in illegitimates the rate for malformations had increased among them by 31 per cent against an average of 53 per cent The actual rates of mortality in Scotland for each of the principal causes were at present much higher than the corresponding rates for England and Wales

The death rate of children aged 1–5 years had shown an entirely different and much more satisfactory course than had infant mortality Improvement could be traced back to 1870 and by the end of the century the rate had declined by 40 per cent. of the level in 1861 Even in the present century considerable improvement had been shown, the rate of decline being relatively greater than in infancy The nearer to infancy the less the improvement, but except for 0–1 years the date of appearance of decline at individual years was roughly the same

SUGGESTED EXPLANATIONS OF THE IMPROVEMENT

As the similarities shown by the improvement were as impressive as the differences when area time, or condition was considered some people had been led to look for some general changes to explain the improvement. The first of these was birth rate several studies had shown a high correlation between birth rate and infant mortality From his own work Dr McKinlay had concluded that the causes which had declined most were those dependent largely on maternal care and, while recognising that improved maternal care could be attributed to child welfare activities he was more inclined to think it resulted from the smaller size of families If the declining birth rate were responsible why did the infant mortality rate not decline before 1900 when the birth rate had declined quite a lot? He did not wish to prove any case but one explanation was that the decline in birth rate had affected the social class which had least effect on infant mortality rate Kermack McKendrick, and McKinlay had concluded from an investigation that the most important factor in the health of an individual during his whole life was his environment up to the end of school life The infant mortality and pre school death rates did not fit in here but might be explained by the dependence of the child s welfare before birth during its first year and to a decreasing extent later on the health of the mother: the mothers of 1901 were born in 1870 or a little later when the death rates of childhood began to fall. Another explanation of the comparative lag was that compulsory education was introduced at a time which would have affected the 1901 mothers there could be no doubt that intelligent motherhood appreciably affected the risks to a child s health The operative factors causing differences in the trend of individual causes of death were very hard to dissociate for instance the decline in infant death rates from diarrhœa might be attributable to child welfare work, but the influence of improved general sanitation and diminished fly prevalence could not be ignored The falling infant mortality had been claimed as a measure of child welfare work The speaker felt that the latter could not be evaluated on the basis of mortality rates and without more extensive knowledge of non fatal intercurrent sickness and defect Uniform methods of assessing deviation from health were needed and called for planned research

DISCUSSION

Dr F Nash welcomed the healthy doubt that the child welfare workers had caused the decline in child mortality

Dr M Radford said there was a tendency to extend social services involving large expenditure of money and time he wondered whether real wages per member of a family could be correlated with the declining death rate If that were so public policy should be directed to altering the purchasing power rather than to delivering goods to the doorstep

Dr M. L Gilchrist asked if the high mortality figures for the central West areas of Scotland could be correlated with the figures for the depressed areas

Dr A Freeman hoped Dr McKinlay would give his views on future trends He would be interested to know if there were any correlation between the introduction of dried milk and the lowered death rate He estimated that if expenditure on infant welfare was the same over Great Britain as in his area the total must be of the order of 3 million pounds

Dr M. Emslie said that in 1928 1¼ million pounds were spent on infant welfare work and half that sum went in buying foods She wondered whether the decline in pre-school mortality could be correlated with the decline in infectious diseases and the coming of hospital treatment

Dr Nora Wattie felt that child welfare clinics were unlikely to have as much effect as improved housing She thought the climate of Scotland must be partly to blame for the mortality there.

Dr E Cassie thought the speaker had taken a pessimistic view; the welfare service had altered the status of the child.

Dr Stella Churchill asked if Dr McKinlay could offer any explanation of the increased incidence of malformation.

The President said that so many deaths due to diarrhœa followed illnesses starting as a cold that respiratory infection was one of the foremost problems The increase in recorded defect might, she thought, be due to change in standards

Dr McKinlay in reply said he had not meant to be derogatory to child welfare but he considered its effects could not easily be assessed from mortality and morbidity rates He wondered to what extent congenital defects and bronchitis and pneumonia could be reduced by visiting guidance and the giving of dried milk. As unemployment relief took size of family into account and wages did not the difference between distressed and other areas was not very great He thought death rates would continue to decline. The claims put forward on behalf of infant welfare achievements were very like those made by those urging better nutrition and better housing

---

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

At a meeting of this section held on Feb 23rd the chair was taken by Sir Charlton Briscoe the president and Dr W G Savage opened a discussion on

Milk as a Factor in the Cause of Disease

He reminded his hearers that as long ago as 1857 an outbreak of typhoid fever had been traced to milk Nowadays the significance of milk as a vehicle of infection was obvious since there were three contributory factors the liability of the cow to diseases transmissible to man the suitability of milk as a culture medium and the large amount of handling between cow and consumer which enabled human disease to be conveyed by the milk. The first group to be considered was the human infection associated with infection of the cow Human tuberculosis of bovine origin could be fairly accurately estimated by bacteriological investigation as infection through tuberculous meat was negligible Dr Savage then estimated the death rate from the Registrar General s figures In 1931 there had been 303 respiratory deaths under five years of age none of them being counted as due to bovine infection Of the 1280 nervous cases 34 per cent and of abdominal tuberculosis 80 per cent of fatal cases in that year were bovine in origin The calculated total was 1731 deaths from bovine tuberculosis This was probably an under estimate The pulmonary tuberculosis of bovine origin was probably higher than the chosen figure of 6 per cent under five and 1 per cent over five; indeed figures of 12·6 per cent had been recorded in local investigations To take 2 per cent instead of 1 per cent would add 300 deaths to the total, making about 2000 in the year 1931 About 4000 fresh cases developed each year, and a vast amount of suffering and expense was caused, quite apart from the death rate On an average, 40 per cent of milch cows were infected, though there were wide local variations About 0 2 per cent of all cows had infected udders and excreted bacilli in large quantities Some 6–8 per cent of all raw milk was infected. The cow was thus an important cause of human tuberculosis Contagious abortion was prevalent among cattle, some 20 per cent showing antibodies in their blood Raw milk samples showed an 8–10 per cent infection, and high class milks were no less liable than "dirty" milks Undulant fever in man was not common, but seemed to be increasing In 1933 over 130 cases had been recorded, with 4 deaths Probably 500 cases occurred annually in England and Wales, according to the calculation of Prof G S Wilson Even so, there was a discrepancy between the human disease and the opportunity afforded by milk. Many farm workers showed latent infection This comparative insusceptibility was not associated with isolation, for the bacillus proved to be always of the bovine type

Streptococcal mastitis in the cow was very common, but consequent sore throat in man was very rare, the usual bovine organism was not pathogenic to man, yet in a few cases mastitis seemed to be infective, probably as a result of udder infection with organisms of human origin It was not easy to infect an udder with a human streptococcus An extensive outbreak in Hove and Brighton in 1929 had been regarded as a new disease, though it was entirely similar to many smaller outbreaks in the early part of the century In the interval few anginal epidemics had been recorded in this country, but a number in America The outbreaks might be very widespread A few scarlatinal epidemics were due to udder disease, and not to the more usual human contamination A few diphtheria outbreaks were also associated with diphtheritic ulceration of the udder Probably udder infection always caused large angina epidemics and not small ones Clinical food poisoning might be traceable to salmonella infection in cows, Dr Savage had records of twenty outbreaks, affecting from one to five hundred persons each The mortality-rate was low, though the disease might be severe Other infections of the cow transmissible to man included anthrax and foot and mouth disease The former was so fatal to the cow that there was little risk to man from the milk. Very few cases of the latter had been recorded in this country, but several in Germany

HUMAN CONTAMINATION

The important diseases spread by human infection of milk were diphtheria, scarlet fever, typhoid fever, paratyphoid fever, dysentery, and occasionally angina The literature, especially annual reports, was full of recorded outbreaks, but it was most difficult to estimate the risk. There were no accurate records The Committee on Cattle Diseases, 1934, gave a list of outbreaks known to the Ministry of Health but admitted its inadequacy It included 14 epidemics of dysentery, 28 of scarlet fever, and 30 of typhoid. In America outbreaks were more systematically recorded or else were more numerous The 1936 outbreak of enteric in Bournemouth and Poole illustrated the wide extent and danger of these outbreaks The Herts paratyphoid outbreak of 1928 and the 1919 Aberdeen outbreak of dysentery were also worth mention In 1920 there had been a diphtheria outbreak at Glastonbury which had never been recorded A milker had contracted the disease and returned from hospital after three negative swabs His younger brother had been allowed to work after one negative throat swab and the result had been 58 direct and 51 indirect cases with 17 deaths There was overwhelming evidence that milk was an important source of disease The milk borne tuberculosis was a national disgrace, since the means of prevention was known Elimination of the use of raw milk would go far to prevent the other milk borne diseases

THE VETERINARY ASPECT

Mr F C MINETT, D Sc, recalled a discussion in 1931 on milk borne streptococcal epidemics and said he would give a "progress report" since that date *Brucella abortus* infection had been studied at the Royal Veterinary College The problem was not simple The incidence depended on a number of factors—e g, the amount of milk tested, the number of guinea-pigs tested, and the technique used These difficulties had been described by E J Pullinger in THE LANCET (1934, 1, 967) Rail tank milks were always infected with tubercle In one investigation 53 out of 63 had been found to be infected with *Br abortus* In another, some 70 per cent of herd samples of clean milks showed infection with *Br abortus* Among ordinary milks 39 per cent of Cheshire milks and 20 per cent of Somerset milks showed this infection. The only explanation of the higher percentage in clean milks seemed to be that it was easier to isolate the organism from clean milk than from dirty, actually the presence of the tubercle bacillus was the complicating factor, as it caused in a guinea pig a state of resistance to the *Br abortus*, so that the brucella could not be isolated. Streptococcal milk borne infections probably arose, as Dr Savage had suggested, from human infections of the udder Streptococcal mastitis was very common and might be due to weakly hæmolytic or actively hæmolytic organisms The former type had no epidemiological significance, as the coccus could not infect man The latter group deserved further consideration Of 82 cases of mastitis examined, 50 were due to the weakly hæmolytic and 13 to highly active hæmolytic streptococci. The cases were not associated with any human disease, so far as was known Since 1931 Dr P R Edwards of Kentucky had shown that the active organisms comprised two subgroups, only one of which caused human disease, being of human origin The two subgroups could be bacteriologically distinguished.

All the evidence pointed to the fact that infection of the milk was via the cow in almost all cases The evidence for indirect contamination was epidemiological, cultural, and concerned with the cow The epidemiological evidence did not explain widespread and persistent epidemics, it seemed unlikely that one man on a farm could cause 500 cases of disease, unless, at least, the organisms grew in the milk. The growth of streptococci in milk at ordinary temperatures had been investigated again It depended on the type of milk, the strain of organism, the numbers put in the temperature and other factors, so that the question was complex Nevertheless, it had been shown that *S pyogenes* would grow slowly in sterilised milk at high temperatures (18°–22° C) but would not grow to any significant extent in raw and pasteurised milk. This was true of three different strains, one of them a human streptococcus direct from the cow It was not easy to find the cow which was the source of an epidemic but human type streptococci had been isolated from cows at times of epidemic The recent Doncaster outbreak of scarlet fever had involved 186 people with 3 deaths and a cow had been found infected with scarlet fever streptococci and kept under observation. Most of the cases started on Dec. 10th 11th and 12th. On Dec 15th the Type II organism had been identified in swabs and next day the same organism had been found in a cow On Dec 24th the samples of milk from the two front quarters of the cow had shown the streptococcus No other cow in the herd showed this organism On Jan 5th the cow had been transferred to the laboratory byre She had repeatedly yielded Type II organisms from the left front quarter during January This was the first time such a cow had been obtained for observation The two front quarters were shrivelled and practically destroyed while the hind quarters were normal. On Dec. 15th the veterinary surgeon had examined the herd and this cow had been normal only on Dec 20th did she show actual mastitis Even on Dec 24th the left fore quarter was described as normal, though the organisms were found in the milk. She showed no sign of malaise or ill health

DISCUSSION

Dr W McD SCOTT drew attention to the group of diseases normally affecting man transmitted to the cow and returned to man in the milk. Enteric might prove to be a rare bovine disease of this type. Droplet infection or hand contamination could hardly explain the large outbreaks traced to one milk supply A recent outbreak had been associated with no human carrier though a secondary case had occurred on the farm. It had been found however that the cows were drinking from a stream polluted with a sewage outflow heavily contaminated with typhoid. Contamination of the milk from the cow's skin or fæces did not seem adequate to account for the widespread contamination of the milk unless the *typhoid bacilli multiplied in the cow's alimentary* canal This practically amounted to typhoid fever in the cows Unfortunately it had been too late to prove the point in this instance

Dr C O HAWTHORNE was impressed by the seriousness of the indictment against milk and doubted if there were any other subject on which there was more decided or unanimous opinion It was strange that men failed to protect themselves One reason might be the delay between infection and manifestation of the disease Public opinion was not thoroughly informed on this subject and the conclusions arrived at by research workers were challenged in the press A recent writer to the *Times* had suggested that only 500 cases of bovine tuberculosis occurred annually Moreover a large commercial interest was involved in the production and sale of milk. Commercial standards of ethics perhaps did not conform to those of scientific and medical men. An advertisement quoted from an official pamphlet statements on the food value of milk but stopped short of the subsequent warning of its dangers About a third of a million of children were receiving raw milk as part of the school ration. The process of popular education must be continued and experts must not remain in academic seclusion but must come down into the arena of the press and show their scientific basis for believing that pure clean milk might be unsafe if not treated by some heat process

Dr TOM HARE suggested that a sense of proportion was essential to medical men and veterinary scientists Exaggeration would not be to the interests of the country or any section of it The uninitiated mind was apt to jump to the conclusion that the cow was responsible for bovine tuberculosis in human beings, whereas there were many sources Bovine tuberculosis was found in the dog and the parrot which had a closer relationship to the human family than the cow Tuberculosis in dairy cattle had been greatly reduced. Was the aim to be the production of a raw healthy milk or a bacteriologically safe treated milk? The leaders of agriculture were not doing a disservice to the country when they emphasised the importance of the consumption of healthy raw milk.

Mr STEELE BODGER *questioned* whether raw milk was as dangerous as had been suggested and thought the milk borne epidemic theory was being overdone. Pasteurisation was attacking the disease problem *from the wrong end and giving a false* sense of security A safe raw milk could be produced for anyone who cared to pay for it No process was more likely to produce slovenly milk than the knowledge that it would be pasteurised for that reason the dirtiest milk in the Midlands was sent to London

Dr J F BROCK emphasised the importance of understanding milk borne diseases and using that knowledge for the benefit of the public. Sometimes the duty of educating the public was forgotten in the desire not to be propagandists Was dissemination of disease to continue until the milk supply could be wholly purified? There must be a short-term policy for the meantime The medical profession did not realise the amount of propaganda against pasteurisation Nor was pasteurisation always adequately done.

Dr RICHARD HAMBURGER said that the medical profession and the consumers in Germany had decided not to use any milk but boiled milk and that there was no difference in the feeding results He could not understand the British idea of the superiority of raw milk. Butter could be substituted for milk in the first two years when the results of bovine tuberculosis were so disastrous and vitamins could always be added.

Dr E G WHITE pointed out that in Germany precautions were taken to ensure cleanliness of the milk before it was boiled In this country medical experts could not express their views in letters to the press because small extracts were published and might give quite the wrong impression Toronto had a very low tuberculosis rate but a very high death rate among children

Dr R. P WILLIAMS spoke of an epidemic of scarlet fever in a sanatorium involving 150 children which could have been obviated by pasteurisation The dairy was attached to the sanatorium and was perfect but one of the dairymen had infected the milk. In another case an apparently normal cow had yielded tuberculous milk and a child had been infected.

Mr BODGER spoke of the Montreal typhoid outbreak due *to pasteurised* milk.

Dr SAVAGE replied maintaining that all alternative sources of bovine tuberculosis had been thoroughly explored and denied any *reduction in* tuberculosis of cows. The Montreal epidemic had not been conveyed by pasteurised milk; the milk in question had not gone through the pasteurising plant.

REVIEWS AND NOTICES OF BOOKS

1 Diseases of Infancy and Childhood

By WILFRID SHELDON, M D, F R C P Lond, Physician for Diseases of Children, King's College Hospital, Physician to Out patients, Hospital for Sick Children, Great Ormond street, Consulting Pædiatrician to the London County Council London J and A Churchill Ltd 1936 Pp 738 *21s*

2 A Handbook on Diseases of Children

Second edition By BRUCE WILLIAMSON, M D Edin, M R C P Lond, Physician to the Royal Northern Hospital, London, Assistant Physician to the Prince of Wales Hospital, London Edinburgh E and S Livingstone 1936 Pp 329 *10s 6d*

1 Now that pædiatrics has received the official benediction of the Royal College of Physicians, in the form of a diploma, one may hope for an increased demand for books on the subject There is likely to be a wider public especially for books supplying a reliable survey of children's diseases in reasonably small compass Dr Sheldon and his publishers have been singularly successful in this new venture The book has none of the signs of prematurity, and indeed the author admits to a period of gestation of over nine years The infant is of pleasing form, and the presentation satisfactory, it is clearly begotten of clinical experience Dr Sheldon has in general followed the conventional plan of discussing the diseases of the various systems seriatim, which makes the book easy of reference and useful in providing an equipment with which to defeat examiners It is naturally less helpful to those who are primarily concerned with the interpretation and significance of symptoms Treatment, however, is considered as fully as is practicable in a book of this size, and if there are signs of a lingering affection for lengthy formulæ, more modern methods have a prominent place The 137 illustrations are, with the possible exception of some of the radiograms, exceptionally good, and add greatly to the interest of the text Dr Sheldon has not hesitated to include rarities, but he is not likely to be accused of any false sense of proportion The book as a whole deserves wide popularity, particularly amongst undergraduate students It is launched in true nautical manner by Prof Still

2 Dr Bruce Williamson's book is smaller and cheaper Whilst it contains little which can justly be criticised, it appears slightly to have reduced a minimum, irreducible except by the expedient of making the subject seem simpler than it really is It has clearly been found of value, and indeed it should serve a useful purpose as a *first* introduction to the subject of children's diseases for students doing their adult medical clerking It would be regrettable if it were looked on as a textbook which in fact it does not claim to be It is attractively bound and illustrated, and of convenient size for the pocket

A System of Clinical Medicine

Tenth edition By T D SAVILL, M D, edited by AGNES SAVILL, M D, and E C WARNER, M D, F R C P London Edward Arnold and Co 1936 Pp 1061 *28s*

IN this well known work symptoms rather than disease entities are the primary material for discussion. After a description of the individual symptom, the common causes are enumerated and elaborated, the symptoms being taken not in alphabetical order but arranged in chapters on the different systems of the body In this edition all sections have been thoroughly revised and much new matter has been introduced, though the size of the volume remains unchanged. The editors have again had the assistance of seventeen collaborators, each of whom is responsible for the revision of the section of the book dealing with his special province, and an expert standard is thus maintained throughout The special features of arrangement and the authoritative material which have made this book popular among generations of students and practitioners are fully maintained in this edition

Medical Diagnosis

Some Clinical Aspects By S LEVY SIMPSON, M A, M.D Camb, M R C P Lond, Physician to the Willesden General Hospital, Assistant Physician, Princess Louise Kensington Hospital for Children London H K Lewis and Co, Ltd General Practice Series 1937 Pp 244 *10s 6d*

TAKE the classified list of diseases from a textbook of medicine, omit the uncommon ones, and add a few common surgical and gynæcological conditions Then under each heading write a succinct little paragraph indicating the nature of the disease, outlining its symptomatology, and mentioning a few points and pitfalls in differential diagnosis Keep laboratory aids in the background but show where their help becomes important Such is Dr Levy Simpson's recipe He has compounded his book very neatly and shrewdly, with a good eye for the clinical essentials, as becomes a pupil of Dr Robert Hutchison The busy practitioner, whose minutes for reading are few, will find it both light and profitable

Bright's Disease and Arterial Hypertension

By WILLARD J STONE, B Sc, M D, F A C P, Clinical Professor of Medicine, School of Medicine, University of Southern California, Los Angeles London W B Saunders Co Ltd 1936 Pp 352 *22s 6d*

Prof Stone has tried to supply the clinician with a concise description of the main features of Bright's disease—no easy task. In carrying it out he refers to many of the better known recent publications and is clearly up to date in his reading His classification is a compromise with obvious *affinities to that of* Addis, thus he divides acute Bright's disease into hæmorrhagic and degenerative types, the former passing by recognisable stages to chronic Bright's disease, with secondary hypertension (or secondary contracted kidney) Under the heading of chronic Bright's disease he also describes the arterio sclerotic kidney with primary hypertension, subdividing this into the latent (or benign) and active (or malignant) types In this classification the influence of the German school is apparent, but many will disagree with the close association of these so called benign and malignant types of hypertension After a series of short chapters on various biochemical aspects of the disease the various types of nephritis are separately described with advice on treatment in which diets are given a prominent place The dietetic ingredients will not always be easily interpreted by those English readers who are unacquainted with the precise nature of Jell O graham crackers and other transatlantic products The work is in general sound and conforms to the more advanced lines of teaching but is often marred by vague statements For instance p 159 Ether anæsthesia has been believed to irritate the glomerular structure of the kidneys and is less frequently used to-day for operative procedures in the presence of infection in children than a decade ago Such comment is worthless unless backed by references and only serves to harass the clinician over his choice of anæsthetic. The author's description (p 121) of a simple and sensitive test for red blood cells in urinary deposits which will enable the detection of amounts down to 1300 per c cm of urine deserves the attention of pathologists in view of the great clinical importance of this finding

Post mortem Appearances

Third edition. By JOAN M. ROSS M.D B S Lond M.R C.S L R C P Reader in Pathology University of London; Morbid Anatomist to the Royal Free Hospital; late Assistant Pathologist to St Mary's Hospital. London Humphrey Milford Oxford University Press. 1037 Pp 243 7s 6d

THIS little book has now established itself as a student's guide Its special feature is the description of typical cases as they appear in the post-mortem room Most of the larger text-books of pathology deal with the changes in the different organs separately leaving the student to learn from practical experience how these changes may be related Dr Ross describes briefly the chief anatomical changes to be expected in a person dying from any of the commoner diseases and thus enables the student to judge how far the cases he sees at autopsy conform to type

The chief alteration made in preparing this new edition is in the section on renal disease which has been entirely rewritten The problem of the classification of nephritis has been tackled in an effective way by preserving the utmost simplicity and by omitting the less important types A useful section of the book is that dealing with death from causes other than disease here the characteristic features of cases of poisoning are briefly but clearly described. Appendices are included with tables of the normal average weights and measurements of the organs The book is excellently adapted to its purpose and its arrangement and indexing make for quick and easy reference

Bailey's Textbook of Histology

Ninth edition By ELWYN and STRONG Revised and rewritten by the Anatomical Staff of the College of Physicians and Surgeons Columbia University London Baillière, Tindall and Cox 1036 Pp 773 27s

THIS revision of the text-book by Adolf Elwyn and Oliver Strong has been undertaken by five members of the anatomy department of Columbia University They have made alterations in nearly all parts, rewriting the four chapters on the cell the blood and lymph muscle and the organs of special sense and replacing some of the old figures by new ones. The system adopted is to explain structure as far as possible in relation to function Much physiological matter is therefore included along with discussions on modern researches An interesting chapter is that on the living cell which describes amongst other things methods of tissue culture; and throughout the book there are frequent references to the study of tissues in the living state. The result is a somewhat lengthy work—perhaps more than the average medical student will be inclined to tackle at first sight—but the reader will soon find compensation for extra bulk in an easy and readable style Since the text-book is intended for students and not as a work of reference no bibliography is included. Information on technique is confined to general terms and no details are given on staining methods. The subject matter is well balanced, and due consideration is given to the bearing of histological problems on those of physiology and medicine. Thus the work forms a good coördinating link in the medical curriculum and in this respect especially it can be recommended to medical students

A Textbook of Bacteriology and its Applications

By CURTIS M. HILLIARD Professor of Biology and Health Simmons College Revised edition Boston Ginn and Co Pp 330 12s 6d

BACTERIOLOGY though it contains so much of general interest is not easy to present in a popular form. This, however is no reason why sincere efforts to this end should be discouraged Prof Hilliard's little book certainly falls into the category of the sincere Except that it does not cater for the needs of any special technical group of bacteriologists it is perhaps hardly fair to call it a popular work The information provided appears to be reliable and is set out in a scholarly way One of the chapters contains a very full synopsis of the classification of bacteria according to Bergey the professional bacteriologist will pity the reader say a dairymaid, a health visitor or an improver in a canning factory who struggles with detail upon which the average expert would not welcome examination One of the best chapters is that on refrigeration and canning Here we read of a consignment of eggs put aside during two years litigation and subsequently sold as entirely sound and safe food material with other interesting matter with which English readers are likely to be unfamiliar A few of the recurring solecisms of text books are allowed to creep in for example Hofmann and Ziehl Neelsen are misspelt and there is some muddle in the description of the unit of diphtheria antitoxin To those who want a conspectus of general rather than medical bacteriology and who are not afraid to assimilate their knowledge in a concentrated form this little book may be recommended

Recent Advances in Allergy

Third edition. By GEORGE W BRAY M.B Ch.M. Sydney M.R C P Lond. Physician in Charge of Children's Department Prince of Wales Hospital; Assistant Physician Princess Elizabeth of York Hospital for Children Consulting Allergist, Children's Hospital Hampstead. London: J and A Churchill Ltd. 1037 Pp 517 15s

IN the days before allergy asthma and urticaria were regarded as neuroses and fell largely in the province of the neurologist There are suggestions that the allergic hypothesis is losing much of its momentum—it has reached the dangerous age of specialised *practitioners* journals and societies—and with the swing of the pendulum the asthmatic is returning for help to the psychologist. One of the most interesting chapters in this third edition of Dr Bray's book deals with the nervous or psychic factor Psychologists and allergists at present adopt towards each other a sceptical or frankly hostile attitude, and until they exchange tactics of catch-as-catch-can for give and take the results will be more amusing than instructive As it is computed that 30 per cent of the population is psychoneurotic and 25 per cent is allergic, they must have a good deal of ground in common In allergy proper the most striking advances appear to have been the recognition of the frequency with which moulds and fungi are responsible for allergic symptoms and the study of drug sensitivity, of which two of the most striking manifestations are purpura hæmorrhagica and agranulocytosis It is difficult sometimes to avoid the feeling that allergists collect allergens as other men collect postage stamps and old china, and until we solve the central problem of the interplay of the soil and the seed, of the nervous system or constitution and the foreign protein, in these curious manifestations of spasm and exudation, allergy will belong to the art of romantic detection rather than the science of therapeutics

This contribution to the "Recent Advances" series now contains more than 500 pages, and has really developed into a text book on allergy Considered as such it is a very able production, but much of the material presented is neither recent nor advantageous, and the book, like some others in the series, would benefit from rigorous pruning If indeed the series is to live up to its title—and it is by so doing that it will continue to earn the gratitude of the profession—the contributors should eschew any desire to be encyclopædical, and confine themselves to critical reviews of recent work.

The Thyroid

Surgery, Syndromes, Treatment By E P SLOAN, M.D Edited by Members of the Sloan Clinic London Baillière, Tindall and Cox 1936 Pp 475 45*s*

WRITTEN by a surgeon who before he died in 1935 had a vast experience of operations on the thyroid gland, this posthumous book deals with this gland mainly from the surgeon's point of view It purports, however, to cover the whole gamut of thyroid diseases, especially that of simple and toxic goitre, and includes also chapters dealing briefly with the parathyroids and thymus, particularly in their relation to the thyroid. Dr Sloan gives an able and detailed account of the surgical anatomy and of the various steps in operative procedures on the thyroid gland, the choice of the anæsthetic and the pre operative management of the case are well discussed

The early chapters on the physiology of the thyroid and on the ætiology and pathology of goitre, however, are disappointing Due credit is given to Kendall for the isolation of thyroxine, but no mention is made of its synthesis by Harington. It is referred to as thyro oxy indol and given Kendall's original formula $C_{11}H_{10}O_3NI_3$, the fact that Harington has since shown it to be a derivative of tyrosine and to possess the formula $C_{15}H_{11}O_4NI_4$ *having been over looked* The author supports the dysthyroidism hypothesis of toxic goitre, which is not accepted by most authorities on the disease "The secretory product or products in thyroxine that complement iodine" he calls *thyroin (presumably the same as* Harington's thyronine), he pictures it as "the active principle contained in the thyroxine molecule that differentiates thyroxine from iodine" *Dr Sloan's* thesis is that this unknown element has a great affinity for, and combines with, the iodine in the colloid, producing "wholesome' thyroxine and that, if iodine is not present in the colloid of the follicle, true thyroxine is not formed and the unknown element enters the circulation as a toxic substance This suggestion, which can hardly be elevated to the rank of an hypothesis, is refuted by the facts (1) that the iodine free compound (which is not "an unknown element" but has a definite formula) has been found to be completely inactive, and (2) that in the early stages of simple goitre, where there is marked hyper plasia and little or no iodine present in the follicles, toxicity is absent

Dr Sloan still held to the view that the thyroid is the seat of the primary disturbance in toxic goitre, against the experimental evidence of the last ten years His frequent reference to toxic goitre as diffuse hyperplastic goitre leads to confusion, especially in the chapter on pathology, and in the first paragraph on p 74 the suggestion that where a simple hyper plasia involves the whole gland and continues uninterruptedly it results in the symptoms of Graves's disease is not acceptable Readers would be advised to pay no serious attention to these early chapters The rest of the book is a valuable contribution to thyroid surgery, and a word of praise is due to the illustrations, especially those of the surgical anatomy and operative technique

History of Modern Morals

By MAX HODANN Translated by STELLA BROWNE London William Heinemann (Medical Books) Ltd. 1937 Pp 338 12*s* 6*d*

THIS book would seem to be written to prove that sexual knowledge has still to wage constant battle with something which the author regards as "Victorianism," and throughout the pages irritation is displayed wherever restraint is exercised against the dissemination of information upon sex matters in any phase, development, or aberration Is it Victorianism —a silly term which may imply a dozen things but which for Dr Hodann would seem to mean hypocrisy —to point out that before knowledge is spread it is necessary that the knowledge should be sound, and that it is practically useful to ascertain that its spread is made where the lessons can be understood and are needed? After a chapter entitled the "Secret of Generation," which resumes in a series of brief notes the functions and mechanisms of sex, the author finds himself compelled to "pursue and dissect the contradictions and cruelties which have grown out of the sexphobia of the nineteenth century" Accordingly we get forty pages dealing with sexual perversion, the case of Prince Eulenburg being given in some detail, while that of Wilde is alluded to in a way that reveals the author's credulity

The chapters dealing with the fight against venereal disease and the history of birth control are quite well done and here an extensive bibliography is well selected, which cannot be said for other sections of the book. But it shows a want of all sense of proportion to describe workers in the various fields of what the author calls "sexology" as "pioneers who are in the uncomfortable position of urging a cosmic evolution" This exaggeration of the effort and object fails to impress readers who know something about the subject, and huge bibliographies which include publications of no importance side by side with really sound work give a wrong impression. Dr Hodann has written an interesting book, but is described on the wrapper as one who "knows the economic conditions of all Europe and the latest conclusions in medicine and psychology,"—and that is a difficult description to live up to

THE LANCET

LONDON SATURDAY FEBRUARY 27 1937

MENTAL DISORDER AND ENDOCRINE ACTIVITIES

THE subject of the combined meeting of the sections of psychiatry and medicine of the Royal Society of Medicine[1] might almost be called inevitable Psychiatry looks everywhere in medicine and indeed sometimes outside medicine for new methods and stimulation It has for centuries been accustomed to look particularly to the study of the nervous system It could not help looking similarly to the endocrine glands when they too were recognised to play an important part in the integrated activities of the body Striking clinical observations as in thyroid disorder indicated that anomalies of endocrine secretion could affect the mind, and mental changes occurring at sexual epochs of life such as puberty and the menopause were naturally attributed to endocrine influences But the assumptions made as to the specific relation of endocrine anomalies to characteristic mental states were unjustified and the hopes expressed as to the efficacy of endocrine replacement or diminution in putting mental disorder right were not realised It did not prove possible to demonstrate in any but thyrogenic disorders the supposedly causal endocrine agent nor did therapy based on such views benefit the patients

With the enormous advances in endocrinology during the last few years the situation has altered There have also been advances in our understanding of the nervous system as Prof GOLLA pointed out which enlarge and illuminate the problem There is no longer an excuse for vague speculation about functions and secretions on which much precise work has been done nor for giving endocrine preparations in an inactive form or ineffectual dose indeed some psychiatrists have lately gone to the opposite extreme in their empirical use of large doses of insulin for producing shock in schizophrenia Moreover both endocrinology and psychiatry recognise complex interrelations where once there seemed an elusive simplicity It is scarcely any longer expected that the emotional and other forms of mental disorder can be laid directly or solely to the door of some anomaly of the ductless glands But with regard to constitution the opinion is expressed sometimes very naively, that it is determined and given its individual character by a combination of endocrine influences This conclusion is tenable for physical constitution if the endocrine secretions are recognised as among the essential mediators—not the originators—of the process of development Since psychiatry led chiefly by KRETSCHMER has accepted the notion of close psychophysical correlation in respect of certain broad types the assumption has been fairly readily made that all the impulses which are the groundwork of character and not merely the sexual ones are influenced by the endocrine secretions Hormic systems have made play with the assumption But unfortunately observations to confirm it are still to seek. It would be hard to say which interpretation of psychic constitution is now the less defensible that which postulates too much of one secretion and too little of another or explanation in loose terms such as ' polyglandular dysfunction and gonadal insufficiency It does not follow however, that our present ignorance in this matter of constitution or in regard to endocrine aspects of mental disorder will continue A very painstaking investigation by Dr WALTER FREEMAN[2] for example though it yielded no clear findings on these points suggested to him that the biological and chemical assay of active endocrine principles in the circulating blood will be a line of advance The speakers at the Royal Society of Medicine s meeting showed how large was the scope of further research

Dr J H SHELDON[3] has lately drawn attention as have some other writers to the presumptive anomaly of pituitary function that may be found in psychogenic ' anorexia nervosa Such observations underline the interdependence of psychological neural and endocrine mechanisms It is in reversible anomalies of function rather than in permanent disease or histologically visible damage of the ductless glands that the psychiatrist s interest lies The extravagant and cloudy guesses which may be read of in historical reviews of this problem[4] are giving place to the sober working out of detailed relationships

THORACOPLASTY IN PULMONARY TUBERCULOSIS

AMONG the papers that appear in the fifth volume of the *Brompton Hospital Reports*[5] is one which records the experience gained during the last fourteen years in the treatment of pulmonary tuberculosis by thoracoplasty It has been compiled by the registrars under the direction of the honorary medical and surgical staff and [illegible] of an objective statement of wha[illegible] happened with a minimum of con[illegible] the period 1922–35, 437 cases were [illegible] method and the yearly figures [illegible] continuous increase in the fr[illegible] cation. At the present time th[illegible] employed in some 6 per cent [illegible] pulmonary tuberculosis [illegible] YOUNG points out in an [illegible] volume is restricted b[illegible] and pathological factors, each of which demands careful consideration in the selection of cases for operation The average operation mortality over the whole period under review has been 14 6 per cent, but has fluctuated rather widely from year to year

It is never easy to evaluate the effect of any method of treatment on an exact quantitative basis, and the difficulties, to which reference is made in our correspondence columns, become formidable when we are dealing with a disease such as pulmonary tuberculosis, which has a very variable natural course Many things that are difficult are, however, well worth attempting, and the comparative assessment of different methods of treating any malady from which man suffers is a problem that clearly falls within this category If it has a special urgency in pulmonary tuberculosis, it is because the discomfort associated with intrathoracic intervention is not negligible, and patients have a right to know to what extent the prognosis is likely to be improved thereby, if this can be ascertained At present, as Dr **Otto May** points out on another page, the insurance companies seldom regard a history of artificial pneumothorax in a tuberculous proposer as justifying more favourable terms than he would get without it, since "the evidence of a definitely better prognosis is still rather scanty" For insurance purposes, he says, the efficacy of thoracoplasty is of less moment, since in the cases severe enough to require such a drastic procedure the terms of acceptance would hardly be affected, and anyway the number of proposers in this category is small But clinically there can be no excuse for failing to follow up cases treated by this method and to ascertain whether, all things considered, they have benefited therefrom The special difficulty in all such inquiries is to devise criteria of benefit that will be generally accepted The basis of evaluation adopted by **Brooks** and **Lander** is the probability of living for five years calculated for each year that has elapsed since the operation In the customary decimal notation, this value is 0 67 immediately after the operation—that is, 67 per cent of the patients are alive five years later—and it rises in each subsequent year until it reaches 0 78 in the fourth post-operative year, beyond which no significant figures are yet available These are compared with figures, published in an earlier report, showing the probability of surviving five years for Grade B3 cases in general, and for Grade B3 cases treated by artificial pneumothorax The corresponding probabilities in these series were, for the cases receiving no special treatment, 0 24 and 0 46, and for the cases treated by artificial pneumothorax 0 55 and 0 59 On their face value, these figures suggest that thoracoplasty is a promising procedure in a limited number of carefully selected cases How far the face value can be trusted is, of course, another question It clearly depends on whether the cases treated by thoracoplasty, the cases treated by artificial pneumothorax, and the cases in which neither procedure was employed were similar in all relevant respects, other than the method of treatment adopted This, perhaps, is hardly likely to have been the case, but if on these grounds we should hesitate to accept the recorded figures as an accurate quantitative description of the relative advantages of thoracoplasty we should certainly not neglect the suggestion that they offer

The staff of Brompton Hospital are to be congratulated on placing these facts on record, and on the way in which the work has been done If the staffs of our voluntary hospitals, working as teams, would observe over adequate periods of time the effects of various forms of treatment in various selected types of disease and report on their findings, we should, within a generation, acquire knowledge which we very badly need

GASTROSCOPY

Gastroscopy[1] in English-speaking countries is still so new that those who write about it write as for the uninitiated Two introductory papers of this kind have recently appeared, one by **Jakob Schloss**[2] from Boston, and one by **Hermon Taylor**[3] from the London Hospital. Dr **Schloss** was formerly an assistant in **Morawitz**'s clinic in Leipzig, where **Henning** did much of the pioneer German work on gastroscopy, and his paper is largely a summary of German opinion and experience, borne out by his own He emphasises the usefulness of a gastroscope with a slightly bent distal end carrying a window directed laterally and a little proximally, which will make visible the pylorus of a J shaped stomach, this is not an alternative but an accessory to the standard flexible instrument With two colleagues, Dr **Schloss** has also published[4] a summary of the results of combined examination of 100 patients with the gastroscope and with the radiographic "relief" method, showing that in difficult cases the one method supplements the other and a larger proportion of well-founded diagnoses can be reached than with either alone Mr **Taylor**'s paper is not merely a descriptive review but also a detailed presentation of his own experience Working as Moynihan fellow of the Association of Surgeons he has made 60 gastroscopic examinations of selected patients He claims part credit for the introduction of the inflatable balloon near the end of the instrument, described in our columns[5] by H W **Rodgers** last year, it can be used to push away, and thereby render visible, areas of the lesser curve that lie close up against the window of the gastroscope, and it is undoubtedly an important technical improvement His records include several cases where doubtful ulcers could be recognised as either malignant or benign, several examples of the discovery of gastric ulcers undetected radiologically, and fourteen cases of gastro-enterostomy where the presence or absence of a stomal ulcer could be established Even with so short an experience he has presented very fair grounds for his view that gastroscopy is a useful diagnostic procedure in cases where radiological examination is not conclusive He also has an interesting note on the difficult problem of gastritis He suggests that the prominence of folds and mammillation of the mucosa that characterise hypertrophic gastritis are not inflammatory changes but anatomical characters of that mucosa and that similarly the thinning of the mucosa in atrophic gastritis is an anatomical peculiarity and not a pathological phenomenon The hypertrophic mucosa and the atrophic mucosa he would refer respectively to HURST s congenitally hypersthenic and hyposthenic types of stomach and he thinks that a gastritis, shown by increased redness, congestion, hæmorrhage loss of sheen and increase of mucous secretion may be and often is superposed on either of them It is an attractive suggestion that should be susceptible of test so far as the grosser changes are concerned, even on post-mortem material Gastroscopy is attracting the attention of an increasing number of both physicians and surgeons in this country Mr TAYLOR s paper with its very good illustrations will be of considerable value to them

ANNOTATIONS

WHAT AN ACUTE GENERAL HOSPITAL SHOULD COST

SOME four years ago the Minister of Health appointed a strong departmental committee to consider the cost of building and maintaining various classes of public buildings including hospitals They were asked to pay special attention to the revision of standards to modern methods of construction and to the possibility of securing economy without loss of efficiency They have had a busy time visiting hospitals and hearing witnesses and have met 38 times in plenary session under the chairmanship of Mr Adam Maitland M P the medical members of the committee being Dr H W Bruce, Dame Janet Campbell Dr J Ferguson Dr Barrie Lambert, Dr T S McIntosh and Dr W Rees Thomas. The report now issued is the first instalment, dealing as it does with a particular type of hospital called conveniently if colloquially the acute general hospital meaning thereby a hospital designed and equipped for first-class medical and surgical work and intended for patients whose condition whether it be acute or chronic, calls for active medical or surgical treatment But much of the ground which has been covered is common to other parts of the subject and need not be gone over again in the later reports The committee is quite definite in its first conclusion that it is not practicable to express hospital standards in terms of cost—there are too many variables—and they have met the apprehension that standardisation may tend to stereotype design and impede progress when admittedly hospital design is in a transition stage, by refraining from publishing standard or model plans and giving only illustrative diagrams They point out too that to divide the total cost of a hospital by the number of patient beds and call the resulting figure the cost per bed is another very fallacious practice. Even the cost of similar hospitals does not vary directly with the number of beds the requirements of different hospitals vary widely and one hospital may have been built as a completed institution while another is planned with a view to early extension Once built a hospital lasts for many years, and the annual cost of maintaining it matters more than the first cost since sinking fund charges are only a small part of total annual expenditure The standards suggested for in patient accommodation are therefore something better than the irreducible minimum and in staff quarters they look to securing a substantial degree of comfort; in such things as operating theatres they have felt it right to be fairly liberal Every page of the report demands careful study but the principal conclusions are set out concisely at the end The standard ward unit is to contain 30 beds 4 of them in one bed rooms although a kind word is given to the recent tendency to replace the main ward by two or more smaller wards The longitudinal arrangement of beds is regarded as an interesting innovation still on its trial; its adoption is not likely to affect constructional cost much one way or the other The standards for main wards are fixed by general consent as height 12 ft (11 ft if fewer than 16 beds) space between bed centres 8 ft width 25 to 26 ft Some of the members would be content with 24 ft On the residential side an administrative sister is to have 240 sq ft for her bed and sitting rooms, a ward sister 140 sq ft for her bed-sitting room the nurses 100 sq ft for bedroom with a bathroom for every 6 to 8 bedrooms The report runs to 84 pages and may be obtained from H.M Stationery Office for 1s 3d

THE TREATMENT OF GRAVES S DISEASE

THE respective merits of the medicinal operative and radiological treatment of Graves s disease are discussed by Dr Haakon Rasmussen [1] of the Haukeland Hospital Bergen, Norway in the light of 98 cases treated in the decade 1924–34 Follow up examinations conducted some time after discharge afforded an opportunity for comparing the merits of these different methods of treatment. Though no final judgment could be passed on the basis of such heterogeneous material and so small numbers this study gives more than an inkling of the merits and shortcomings of the methods of treatment under review It may be said at once that conservative treatment does not emerge from this comparison with flying colours although the cases enjoying it were relatively slight. Of 48 patients whose treatment was limited to strict rest in bed a vegetarian diet, and the administration of iodine, sedatives &c 42 were traced In 14 or possibly 16 cases relief of thyrotoxicosis had been achieved but the majority still suffered from psychoneurotic manifestations which sometimes greatly reduced the working capacity of these patients who could not therefore be considered as cured Indeed only 4 of the 42 could be regarded as completely symptom free and cured In as many as 18 cases conservative treatment seemed to have had no influence on the course of the disease but counterbalancing this observation is the fact that 10 patients were fully fit for work Though this group of 42 represented on the whole comparatively mild forms of the disease as many as 8 of the patients were found to have died in the short period under review their Graves s disease having contributed in some degree to the fatal issue in several of these cases The follow up findings in the 41 cases treated by thyroidectomy were also not particularly cheering unless account be taken of the seriousness of the pre operative condition of many of these patients In 28 cases there was no evidence of thyrotoxicosis, but only five or six of these 28 were wholly rid of their symptoms, and could be considered as cured, the remainder had various psychoneurotic symptoms Further, 7 patients still showed signs of thyrotoxicosis, and 6 suffered from permanent hypothyroidism or myxœdema Tetany was observed in 2 cases, and paralysis of the recurrent laryngeal nerve in 4 Permanent hoarseness and asthma had developed as a sequel to the paralysis of the recurrent laryngeal nerve in one case There were also minor troubles such as discomfort on swallowing due to adhesions in the field of operation To lighten this gloomy picture it should be noted that 26 of these patients were fit for work, though many of them had not achieved full working capacity till a year or two after operation. The radiologically treated group was comparatively small. Of the 10 patients thus treated 8 showed no signs of thyrotoxicosis on re examination, but most of them still suffered from the psychoneurotic symptoms, and a complete cure could be claimed in only two or three cases Dr Rasmussen's discussion of the comparative merits of operative and radiological treatment betrays no strong bias either way, and all who are interested in this subject would do well to read the judicious summing up in his paper which is published in English

THE DEVELOPMENT AND STRUCTURE OF THE SKELETON

EXPERIMENTAL morphology is fairly new and its exponents are mostly those who have actually taken some part in its development especially during the last few years many excellent monographs on the subject have made their appearance The latest[1] is a critical summary by Dr P D F Murray, and though it consists mainly of a review of recent work it includes a certain amount of unpublished research done by Dr Murray himself and other workers at the Strangeways Laboratory The most important developmental fact which emerges from the welter of diverse opinions and results is the fundamental distinction between the primary cartilaginous skeletal element and the bone which replaces it The first is determined by forces inherent in the organism, but the second taking the general shape given to it by the structure it replaces, is yet but the material employed in the play of many and varied external forces which seem to be solely responsible for its final form and constitution

Now and then one is struck by the crudity—we had almost said childishness—of some of the hypotheses advanced by the experimenters in this field (and not in this field alone) to explain their results They seem in a hurry to bring forward purely physical explanations of the simplest sort in matters which are plainly organismic A survey of the stores of related facts garnered by the older morphologists would surely be of value to the experimenter, enlarging and modifying his outlook considerably, the old morphology and the new must meet and agree if progress is to ensue and the sooner the better The problem of the appearance of the cranial membrane bones for example illustrates clearly this need for correlation Some at least of the hypotheses brought forward to account for the existence and limitations of these bones would have been suppressed if their authors had considered a wider morphology The ingenuity displayed in explaining the appearance of these bones in situ in the human head would have been recognised as misplaced had the bones been followed back into reptilian classes or even lower, and such notions as pressure from the brain would not have been suggested as one of the factors of determination Among the observations recorded by Dr Murray on this subject two seem to us of great interest, and apparently not in opposition—notably the views of Kokott and of Troitsky These hypotheses still lack the embryological evidence in the vertebrate classes which would lift them to the level of reasonable theory, but doubtless this will be supplied in the future Dr Murray has put together in an engaging shape records of experimental work not only on bones but on the form of joints and false joints, this work will certainly modify the views of those concerned with the pathology of these structures

WATER BALANCE AND THE MENSTRUAL CYCLE

THE minor ailments and dislocations of physiological equilibrium that often attend menstruation offer a rich source of material for both clinical scientist and physiologist, and there are signs that recent discoveries in endocrinology are leading to its investigation One of the commonest, though not the most distressing of these abnormalities, is a rather abrupt retention of fluid which sets in during the last few days of the cycle, reaches a peak at or about the onset of menstruation, and disappears rapidly as the flow is established As a rule the symptoms are trivial. Slight thirst, a sharp rise in body weight, and a feeling that clothes are too tight, may be all that is noticed, but direct evidence of waterlogging, in the shape of pitting œdema of the legs, is not rare What relation, if any, this menstrual œdema bears to the waterlogging of pregnancy and the gross œdema of pre-eclampsia is not clear, but it is permissible to suspect that the three may have something in common

These facts lend particular interest to the observations of P L Krohn and S Zuckerman[1] on cyclical observations in the water balance of Old World monkeys The monkey is endowed (or cursed) with a sexual cycle which resembles that of woman in the appearance of menstruation at intervals of about 30 days The simian cycle, however, is distinguished by an additional set of phenomena which reach a climax in ovulation about midway between successive menstrual episodes These additional changes seem to correspond to œstrus in the lower mammals and comprise gross swelling of the genital region, apparently composed of fluid, but not, like simple œdema, displaceable by pressure Krohn and Zuckerman noticed that the ebb and flow of the swelling was accompanied by a considerable and parallel rise and fall in body weight, and they decided to find out whether the latter could be attributed to gain and loss of body fluid Adopting principles familiar to students of metabolism, they accordingly made daily measurements of the various fractions of fluid intake and output and so obtained estimates of the total water exchange Such estimates are necessarily approximate, but the fluctuations described seem well outside the limits of experimental error.

[1] Bones A Study of the Development and Structure of the Vertebrate Skeleton By P D F Murray M A D Sc. Cambridge The University Press 1936 Pp 203 8s 6d

[1] *J Physiol* 1937 88 369

It appears that during the pro œstrus phase of genital swelling which begins during or at the end of menstruation there is progressive retention of water which is rapidly corrected as the swelling subsides The kidney seems to bear the brunt of these fluctuations for the output of urine falls at first, and rises abruptly after ovulation. It seems clear that the change in body weight can be fully accounted for by these shifts of body fluid and the latter in turn seem largely if not wholly due to the local changes in the sexual skin for which finally the œstrogenic hormone is responsible What relation these phenomena in the ape bear to menstrual œdema in women is at present uncertain It has been pointed out above that the latter begins to appear shortly before menstruation at a time when the corpus luteum is morphologically at least in the ascendant In the ape in contrast the œdema is greatest at a point diametrically opposite in the cycle—namely when the follicle is ripe and the luteal phase at its lowest ebb Moreover in women the œdema is generalised and ovulation is not attended by noticeable swelling of the genitalia. These facts seems to suggest that the phenomena in the two species are entirely different in origin. On the other hand, there is still some discrepancy between the morphological and the biochemical changes in the sex cycle The excretion of œstrogenic hormone for instance although greatest at the time of ovulation is known to rise to a second peak just before menstruation. The significance of this second peak is not at present clear Little is known about the ability of the tissues to destroy store or utilise sex hormones, and the rate of excretion or the concentration in the blood of œstrin may give misleading impressions about the rate of secretion of the hormone. It is therefore possible that despite chronological and anatomical differences the menstrual œdema of woman may be in some way related to œstrous swelling in the ape.

ABNORMAL FINGER PRINTS

Dr Wolfgang Abel assistant in the Kaiser Wilhelm Institute for Anthropology in Berlin has made some interesting observations[1] on certain abnormalities in finger prints He shows that there is a tendency for the pattern to be distorted over a particular area of the finger and that a remarkably similar area is affected on the same finger of the other hand From a study of fœtal development he has established the fact that the whole of the normal pattern does not appear at once some parts of it developing before others The region of the pattern which is most often abnormal is that which appears last in normal development He therefore concludes that the abnormalities are induced at this particular stage of fœtal life His suggestion as to the cause of these abnormalities is not very easy to follow The type of normal finger print is related he says to the convexity of the finger surface and this in turn is dependent upon the tension of the underlying tissue The abnormalities can be recognised as local developments of one type of pattern on a finger which was previously developing another Such a change must therefore he concludes be due to internal changes of tension and to confirm this he cites a single observed example of a fœtus whose left hand had been constricted (presumably by the cord) in the uterus The finger prints of this hand developed typical abnormalities while the other remained normal. This Dr Abel regards as corroborating his tension theory and he would like to see his observations followed up since it is known that other abnormalities (bodily and mental) tend to be associated with abnormal finger prints

FAMILY DOCTORING IN THE XVII CENTURY

WHEN William Russell, fifth Earl of Bedford, wanted to know how much ready money he had at his disposal he had only to look into the great trunk which stood in Bedford House in the Strand and served as the family bank through which all the finances of his establishment were managed The rents and dues received from the stewards of the various estates of the family were placed in it and when any money was paid out, whether it be £120 to buy satin and brocade for the Earl and his son to wear at the coronation of Charles II or one shilling in November 1681 to be given to the page for twice cutting his hair it was taken from this trunk and the amount noted in a small stout parchment-bound account book. The increasing complexity of these accounts as the family s style of living became more luxurious is demonstrated in Miss Gladys Scott Thomson s entertaining analysis of the Russell budgets from 1641 to 1700[1] From these detailed accounts we learn a great deal of the everyday life of these people what they wore, what they ate, how they educated their children what they spent on their amusements what they planted in their gardens how they visited Bath and Tunbridge Wells, and how they filled their libraries and wine-cellars

One of the earliest items in the book (in August, 1641) is the sum of £20 paid to Dr Clarke for his pains going to my lady of Bedford when she was sick of the smallpox at Woburn with another £2 4s to the hackney coachman that carried him there. The countess recovered and when the family returned to town the disinfection of the house was carried out by Anthony the porter who was given five shillings for pitch and frankincense to smoke the house and yard. Sometimes the doctor appears to have been paid in instalments for in May 1642 £20 was paid to a Dr Caleb Rawlin (or Rawlings) in part of the £40 which he is to have for the cure of my little lord s legs Modern dietitians would be interested in the entry of fourpence in April 1653 which went to buy scurvygrass, or gittings to put in the children s ale The Earl was responsible for the health of all his household and the principal doctors who attended were Sir John Micklethwait and Sir Edmund King and a Frenchman Dr Charlot. They did not, however always visit their patients sometimes the tutor himself an amateur leech would write describing the illness and the doctor would reply by letter saying how it was to be treated. Other minor medical attendants were the corn cutter and the barber who came to cure the toothache and to bleed the household regularly in turn. A great many remedies were also fetched from the apothecary at Aylesbury and we read of Betty Buskin the laundry maid receiving a vomit and Mr Robert s footman a plaster and oil of St John s wort Many forms of scurvy occurred both among the family and the servants (in spite of the gittings) and were treated with antiscorbutic tincture and chalybeate water Most of the nursing of the sick was done by the wives or the daughters of men employed on the estate, of whom the favourite was the gardener s wife When a disease was infectious the nurse was sent to live apart with the patient and was entirely responsible for his care board and lodging Miss Thomson has chosen some beautiful portraits to illustrate her description of life in this family

A STUDY OF HEPATIC ŒDEMA

THOUGH much work has been done on œdema in other parts of the body, œdema of the liver has had little attention Keschner and Klemperer[1] have now studied its incidence in 505 unselected autopsies and in a further selected series The condition was diagnosed histologically when the capillary walls could be seen to be separated from the liver cells, and when the pericapillary spaces were distended by a granular (protein) material which could be stained. Of the 505 unselected cases 79 showed these changes "Back pressure," attributed to cardiac failure, accounted for nearly half of these Of all the cases of cardiac failure examined 39 per cent showed hepatic œdema, yet of 9 cases of lipoid nephrosis with generalised œdema not one showed it There were 60 deaths in uræmia and they gave the following interesting results of 24 cases under the heading of "malignant nephrosclerosis" no less than 18 had hepatic œdema, while of 36 cases of uræmia due to causes other than this, such as pyelonephritis and polycystic kidneys, only 14 showed the change Hepatic œdema was commoner in influenza than in any other infectious disease, and it was noted in 5 out of 11 cases of diabetic coma It was also common in association with exophthalmic goitre Keschner and Klemperer refer to the type of hepatic œdema that follows back pressure as "mechanical œdema" and to the other variety, in which there can be no factor of back pressure as "primary œdema," and they suggest that it is due to increased permeability of the capillary wall They claim that the demonstration of primary hepatic œdema is at present the only morphological evidence of increased capillary permeability

DERMATOLOGISTS ON ALLERGY

MUCH of the early work on allergy by Pirquet, Bloch, Low, and others concerned the skin, and many of the most spectacular exhibits of allergy are cutaneous On the other hand, the dermatologist must beware of too readily invoking allergy as an explanation, just as the general physician must think twice before he allows the allergic hypothesis to be extended to cover most of the type reactions that make up constitutional medicine The practical mind will not at present accept more than a small proportion of medical disorders as being built upon this specific pattern, and Goldsmith[2] and Dowling[3] think it unjustifiable even to argue that all cases of eczema and urticaria are reactions of the antigen antibody type Dr Dowling believes that the general assumption that atopic eczema—that is, eczema of the inherited diathetic type—is due to food allergy is false, and probably most dermatologists will agree with him Dr Goldsmith draws attention to the existence of "latent allergy," in which a positive intracutaneous test is present—usually as the result of exposure—but there are no clinical manifestations He also emphasises the importance of adventitious factors thus a ringworm infection of feet may determine a sensitisation of hands to fur dyes, or an attack of erysipelas may determine sensitisation to quinine in a patient previously tolerant of the drug There is much that is confusing in the subject and nothing more so than the irregular relationship of intracutaneous tests to clinical behaviour In infantile eczema the positive reactions to egg white, cow's milk, and other common allergens have rarely if ever any relationship to the eczema Dermatological medicine inevitably has a certain simplicity and honesty, for the dermatologist, more than most clinicians, sees his failures on the surface Hence the significance of these rather discouraging reports Unfortunately, like most fashionable theories, allergy has left a trail of disappointments, and we must take care not to deceive ourselves or our patients with its mysteries

THE CHEST LEAD IN THE DIAGNOSIS OF CARDIAC PAIN

IT is well recognised that the electrocardiogram can be of great value in the diagnosis of cardiac pain, particularly when the symptom is atypical, as when the pain is a minor complaint or its situation unusual, but like all instrumental methods it has its limitations Diagnostic changes may be lacking under certain conditions, the area affected in myocardial infarction may be too small to produce them, the tracing may not be made at the right time to detect transient changes, being either too early or too late, or the plane of the leads may be unsuitable for recording the changes Myocardial infarction sometimes has an ingravescent onset, with mild pain of one or two days' duration before the typically severe symptoms arise During this initial period, as reported by H Feil,[1] the ordinary electrocardiogram may show little or no change, but more significant alterations may be shown by the chest leads—that is, by the curves obtained when one or both electrodes are applied directly to the chest wall. These have been extensively studied during the last few years, especially in America, and it has been shown that in coronary disease there may be characteristic changes similar to those seen in the standard leads The results have been complicated, however, because of the variety of ways in which the electrodes have been applied, each method giving a different picture under the same conditions

Dr Willcox and Dr Lovibond have investigated the changes in a chest lead (termed lead IV) in 102 patients with coronary disease, applying the left arm electrode over the heart and the right arm electrode to the back of the chest, and they record their results on p 501 With this method the initial ventricular deflection and the T wave are upright, and it has an advantage over other ways of disposing the electrodes in that the curve is comparable to that normally obtained with a limb lead In 62 patients with effort angina, they found 8 who showed changes in lead IV suggestive of coronary disease, but whose standard electrocardiograms were normal In a further 40 patients with acute coronary occlusion, there were also 8 in whom the diagnostic changes were confined to the chest lead All of these had anterior apical infarctions, in posterior infarction lead IV was of no help, since it was altered less often than the standard curves and never independently In addition it was found that lead IV was of some value in localising the site of an infarction, confirming the indications given by the standard leads, or supplementing them so as to allow the diagnosis of involvement of both anterior and posterior walls of the left ventricle These results suggest that lead IV is chiefly of value in the diagnosis of anterior lesions, when the changes may occur earlier and last longer than those in standard leads Dr Freeman also reports on p 400 results obtained in acute coronary occlusion with another type of chest lead. His three patients all with typical symptoms showed limb leads characteristic of anterior infarction and in all cases the chest lead was confirmatory though because of the different position—he applies the left-arm electrode to the left foot and the right arm electrode over the apex—the alterations in the waves were in the opposite sense to those recorded by Willcox and Lovibond.

---

[1] Keschner H W and Klemperer P (1936) *Arch Path* 22 583

[2] Goldsmith W N (1936) *Brit J Derm* 48 593

[3] Dowling G B, *Ibid* p 601

[1] *Amer J med Sci* January 1937, p 42

The chest lead appears therefore to have a definite value in the diagnosis of effort angina and of acute coronary occlusion since in a minority it shows significant changes that are absent from the curves obtained with the limb leads though this may be true for only a limited period of the disease It is also clear that the reverse occurs—that is these changes may be confined to the limb leads A confident diagnosis of both coronary occlusion and effort angina can of course be made from symptoms alone when these are typical in the absence of change in the standard electrocardiogram; but with an atypical clinical picture and a normal tracing from the limb leads there is the possibility that valuable evidence may be obtained from a chest lead There are now sufficient data to warrant using this lead in atypical cases, and further investigation may justify its use as a routine It is to be hoped that the exact disposition of the electrodes to the chest wall will become standardised and the method adopted by Willcox and Lovibond with the left arm electrode over the heart seems to be the best

TUBERCULIN POSITIVE CASES WITH NEGATIVE RADIOGRAMS

THE pioneer work of Heimbeck and his Norwegian colleagues has taught others to seek in probationer nurses answers to some of the unsolved problems of early pulmonary tuberculosis The more this material is examined the more does it impress research workers with the facilities it provides for controlled tests. And it has become a rule in certain hospitals abroad for probationers to be tested with tuberculin and to be kept under X ray and skin test supervision throughout their hospital careers during which the changes from a negative to a positive tuberculin reaction can sometimes be correlated with certain exposures to infection In many hospitals in Finland probationer nurses are tested with tuberculin as a routine measure; and in a recent publication[1] Dr Ivar Wallgren has reviewed his experiences with between 700 and 800 tuberculin tested nurses In the Finnish-speaking community only about 13 per cent gave a negative reaction to an intracutaneous injection of 1 mg of tuberculin, whereas among the Swedish-speaking probationers the proportion of negative reactors was about 70 per cent The most instructive observations however concerned the 41 nurses whose tuberculin reactions changed from negative to positive during their training In 30 of these there were no symptoms no clinical phenomena indicative of a tuberculous infection but in the remaining 11 the transition was associated with such symptoms as fever lassitude headache pain in the chest and so forth The radiological examinations of these 41 nurses were negative; in only 3 cases could shadows indicative of intrathoracic tuberculosis be found The primary focus of disease such as Ranke described a score of years ago would therefore seem to be seldom demonstrable in association with very early tuberculous infection Yet in Wallgren's view these nurses must have harboured a primary focus of tuberculosis in their lungs, however negative the radiological examinations may have been. In support of this opinion he gives an account of three cases in which the radiological examination proved negative although a few days later post-mortem examinations revealed recent primary tuberculous lesions in the lungs These observations need not necessarily discredit the radiological examination as a guide to early tuberculosis The evidence which the radiologist can adduce in favour of his speciality in this field is convincing enough. But between the first appearance of a positive tuberculin reaction and the first appearance of radiological shadows indicative of tuberculosis there seems to be an interval.

PRONTOSIL IN ERYSIPELAS

THE clinical evaluation of Prontosil and its derivative p aminobenzenesulphonamide is far from complete, and therapeutic studies on an adequate scale have so far fully demonstrated its capacity only in puerperal fever and in erysipelas Further testimony to its value in erysipelas is presented by W Becker[1] who compares the results in 50 cases with those in the same number treated by other methods the spread of the disease was always arrested and its duration much reduced more so by oral administration of prontosil than by intramuscular or intravenous Local application was found to be useless as is fully to be expected. It is tempting to speculate on how far the amenability of different streptococcal infections to this treatment depends on their morbid anatomy the lesion in erysipelas is highly vascular and since the drug circulates in the blood it seems reasonable to suppose that this is a factor favourable to its action Its effects in other forms of surgical sepsis on otitis media and its complications including meningitis and on scarlet fever still remain to be studied on an adequate scale We publish elsewhere in this issue two clinical notes on cases so treated in one of which sulphæmoglobinæmia developed and certainly contributed to a fatal result This complication which in previous records has been rare and only transient must evidently be watched for contributory causes may perhaps be identified and the condition thus avoided. Meanwhile prontosil is being tried for a number of other purposes Becker himself records complete failure in the treatment of gonorrhœa which is of interest in view of the fact that encouraging experimental results have been reported with the closely related meningococcus He also briefly mentions good results in urinary tract infections a claim recently made more forcefully by H G Huber[2] who treated 14 such cases in children with what appeared to himself striking success These more speculative therapeutic essays will be better interpreted when the experimental work which has placed the treatment of hæmolytic streptococcal infections on so sure a foundation has been extended to other bacteria Since this treatment is now being adopted on an increasing scale and indeed should always be considered in puerperal and surgical sepsis due to Streptococcus pyogenes it may be useful to state again in what forms this remedy is obtainable The original prontosil which was marketed in two forms for administration by injection or by the mouth is now believed to act only by conversion in the body into *p* aminobenzenesulphonamide (referred to variously as "sulphonamide" or "sulphanilamide") Since this substance itself can also be given, and by the mouth, the present tendency appears to be to substitute it entirely for the original product Sulphonamide is obtainable from the manufacturers of prontosil under the name of Prontosil Album, and from many other firms under different names The attachment of trade neologisms to chemical compounds of perfectly defined and even simple composition has always been a source of confusion, and the profession can combat this minor evil and at the same time be sure of obtaining what they really mean by using wherever possible only the proper chemical name of the reagent ordered

THE TOXIC PROPERTIES OF BURNED TISSUES

EXPERIMENTS in the department of surgery of Edinburgh University have led W C Wilson and his collaborators to regard toxins produced in the burned tissues themselves as the harmful agents in burns[1] It will be recalled[2] that their method is to collect œdema fluid from burned areas on the abdominal wall of rabbits and inject it into healthy rabbits and into mice Intravenous, subcutaneous, and intraperitoneal injections were used Precautions were taken to avoid injury to internal organs by heat, and to produce œdema without skin necrosis and without an external wound that might become infected with bacteria Flaps of sterilised skin were raised and their *under* surface burnt by application of diathermy The flaps were sutured back into position, and the œdema fluid collected at varying intervals with full aseptic precautions Toxicity developed slowly At four hours after injury the fluid was harmless, at forty eight hours it was often lethal There appeared to be two types of toxin, one of which was rapidly fatal, acting apparently as a nerve poison, and having some properties in common with histamine The slower acting toxin did not cause death for a considerable number of hours The only indication of its mode of action was degeneration of the liver cells frequently found post mortem Samples of fluid which had caused death within a few hours were tested by injection into anæsthetised animals they produced a most striking fall of blood pressure, and this occurred in the presence of a vigorously beating heart and an active vasomotor centre Some animals died in generalised convulsions a few seconds after injection, others lived a few hours and showed signs of muscular weakness, quickening of the pulse, pallor of the ears, laboured respiration, and falling temperature In the animals that survived for days there was often a period of apparent recovery before the final collapse A few ultimately recovered

Bacterial action does not account for the development of toxicity in the œdema fluid, for it was shown to be independent of the results of culture experiments made on the fluid before its extraction When special precautions were observed in taking the fluid for culture it was found to be nearly always sterile That fluid extracted up to four hours after burning is innocuous on injection proves that there is no inherent toxicity of the tissue fluids Saline emulsions of normal skin and emulsions of skin made immediately after burning are equally harmless Efforts to identify the toxin chemically were not altogether successful. It appears to be associated with the globulin fraction and to be of a higher order than amino acids and polypeptides A complete proof of the toxic hypothesis requires a demonstration of the presence of toxins in the blood of burned animals In the experiments so far carried out the burned animals themselves did not show ill effects, but as the extent of tissue burned was limited and the development of toxicity slow, it is probable that only small amounts of toxin were being absorbed The animals were all killed within forty eight hours of the burn, they were not allowed to survive after excision of the burned flap of skin

TREATMENT OF MYASTHENIA GRAVIS

Hyland[1] of Toronto describes the effects of several well accredited methods of treatment upon six patients suffering from severe myasthenic weakness He found that neither physostigmine (eserine) salicylate by mouth nor Antuitrin by intramuscular injection had any apparent influence Irradiation of the thymus gland with X rays was followed, in some cases only, by a remission lasting 4–12 months A combination of glycine (5–15 grammes) by mouth with ephedrine (0 25 g three to five times daily) by subcutaneous injection brought more lasting improvement, but its action varied much from patient to patient, and in the same patient on different occasions In four cases dramatic relief of weakness followed the use of Prostigmin, but this was transient and a caveat is entered against repeated administration of this drug on the grounds that it may be followed by alarming deterioration This is perhaps to exaggerate the dangers, and the statement that prostigmin is "impracticable for continued use" cannot be accepted since there are already several cases on record in which quite large doses of the drug have been given daily for over a year without ill effect Although, as Hyland says, "the increased usage of the muscles permitted during the temporary remission may prove actually harmful if repeated too often," no harm is likely to be done if the patients are warned against over exercise of their newly returned strength

PRINCIPLES OF MEDICAL STATISTICS

IX.—FURTHER EXAMPLES AND DISCUSSION OF χ^2

THE χ^2 test has a wide applicability and forms a useful test of significance in many medical statistical problems, especially those in which the observations must be grouped in descriptive categories (as in the state of nutrition) and are not capable of being expressed quantitatively. Some further examples of its use may therefore be supplied.

A TEST OF DIFFERENCES BETWEEN SERA

Let us suppose that batches of serum from different groups of donors are used for the prevention of measles and give the results shown in Table IX. (The actual figures are imaginary though the example is drawn from the London County Council report on the measles epidemic of 1931–32.) The value of serum in general is not here in question, the assumption being made for the purposes of this illustration that it has value. The proportion of the total 700 children who after exposure to infection and the administration of serum escaped attack was 73 per cent., but between the different serum groups the proportion varies between 53·8 and 90·0 per cent. Taking into account the numbers of children upon whom each serum was tested, are the different degrees of success in the prevention of measles more than would be likely to occur by chance? Or is it likely that the sera are all equally valuable and the departure *from uniformity in the results would be quite likely* to occur in groups of the size used?

TABLE IX.—*Measles Incidence and Serum Treatment*

Serum No.	Number of children in group	Number of children in whom measles was prevented		Number of children in whom measles was not prevented		Percentage of children in whom measles was prevented
		Observed number	Expected number	Observed number	Expected number	
1	120	80	(*87·6*)	40	(*32·4*)	66·7
2	150	135	(*109·5*)	15	(*40·5*)	90·0
3	90	59	(*65·7*)	31	(*24·3*)	65·6
4	90	68	(*65·7*)	22	(*24·3*)	75·6
5	110	87	(*80·3*)	23	(*29·7*)	79·1
6	60	42	(*43·8*)	18	(*16·2*)	70·0
7	80	43	(*58·4*)	37	(*21·6*)	53·8
Total	700	511	(*511*)	189	(*189*)	73·0

As a first step we presume that an equal degree of success should have been observed in each of the groups; we then measure the observed departure from this uniformity and see whether such departure is compatible with our hypothesis of all the tested sera being equally valuable. As the expected degree of success with each serum on this hypothesis we use the proportion of successes observed in the total—i.e., 73·0 per cent. Applying this proportion to each of the groups we find the number of children in whom we expect measles to have been prevented or not prevented (the italicised figures in parentheses, e.g., 73 per cent. of 120 is 87·6). We observe, for example, that with serum No. 2 considerably more children escaped attack (135) than we expect on our hypothesis of uniformity (109·5). On the other hand, with serum No. 7 fewer children escaped attack (43) than we expect on our hypothesis (58·4). Are these differences more than would be likely to arise by chance?

χ^2 is the sum of the fourteen values of (observed number–expected number)^2 ÷ expected number, e.g., $(80-87\cdot6)^2 \div 87\cdot6 = 0\cdot66$; this sum equals 47·42. Only six expected values have to be calculated independently by simple proportion from the 73 per cent. value in the total that we took as the degree of success anticipated with each serum; the remaining values can be calculated by subtraction from the totals at the side and bottom (e.g., if 87·6 of 120 children are expected to escape attack 32·4 must be expected not to escape attack). Or by the formula $n = (c-1)(r-1)$, $n = (2-1)(7-1) = 6$. The published tables of χ^2 *must therefore be entered* (i.e., consulted) with $\chi^2 = 47\cdot42$ and $n = 6$.

From Fisher's table it will be found for these values that P must be considerably less than 0·01, since the table shows that when $n = 6$ P is 0·01 when χ^2 is only 16·81. Here we have a χ^2 nearly three times as large (outside the range of this table). More extensive tables (Tables for Statisticians and Biometricians issued by the Biometric Laboratory of University College, London. Cambridge University Press. 2nd edition, 1924. 15s.)[1] show that P is less than 0·000001. In other words, if our hypothesis that the sera are all equally valuable in prevention of measles is true, then *less than once in a million* times in groups of children of the size here tested should we reach merely by chance results which departed from that uniformity of success to the extent that we have observed with these children. We may therefore reject our hypothesis and conclude that these results differ by more than is likely to be due *to chance, that, all other relevant factors being equal,* some sera were more efficient than others.

Whether we need the more exact probability taken from the larger tables is rather a matter for the individual to determine. If P is less than 0·01—i.e., one in a hundred—then we may perhaps be content to say, without finding any more accurate probability, that the departure from uniformity is an unlikely event to occur by chance. Many statisticians, as pointed out in the last section, take $P = 0\cdot05$ as a conventional level of significance—i.e., if P is greater than 0·05 then the observed values do not differ from the expected values by more than might reasonably be ascribed to chance, while if P is less than 0·05 then it is likely that they do differ by more than might be ascribed to chance. The smaller the value of P the smaller clearly is the probability that the differences noted are due to chance.

THE HOURLY DISTRIBUTION OF BIRTHS

In Table X distributions are given of a series of live and stillbirths according to the time of day at which they took place. With live births the figures suggest that a high proportion of the total take place during the night and a smaller proportion during the early afternoon and evening. With stillbirths rather the reverse appears to be the case, the proportion during the night is somewhat low while in the morning and afternoon the number i rather high, though the differences are not very uniform Are these differences between the numbers recorded at the various hours of the day likely to have occurred merely by chance in samples of the observed size ? On the hypothesis that they have occurred by chance, that live and stillbirths are both distributed evenly over the day, the number of live births in each three hourly period should be 4028 and the number of stillbirths 159 (32,224 − 8, and 1272 − 8) These are the expected values on the hypothesis of uniformity

---

[1] These tables are so constructed that they must be entered with $n + 1$ instead of with n.

TABLE X—*Distribution of Live and Stillbirths over the Day*

Time interval	Number of live births observed	Observed number—expected number	Number of still births observed	Observed number—expected number
Midnight–	4 064	*+36*	126	*−33*
3 A M –	4 627	*+599*	157	*− 2*
6 A.M –	4 488	*+460*	142	*−17*
9 A M –	4 351	*+323*	195	*+36*
12 noon–	3 262	*−766*	150	*− 9*
3 P M –	3 630	*−398*	178	*+19*
6 P M –	3 577	*−451*	144	*−15*
9 P M –midnight	4 225	*+197*	180	*+21*
Total	32 224	0	1272	0

For each distribution, live and stillbirths, eight values of ((observed–expected) ^{2} — expected) have to be calculated Their sum is χ^2 With live births χ^2 equals 413 0, with stillbirths it is 23 8 (It may be noted that as the expected value is the same throughout, the quickest way of calculating χ^2 is to sum the squares of the (observed–expected) values and divide this total by the expected number, instead of making separate divisions by the expected number in each instance) In both sets of data $n=7$, for one value is dependent upon the total of the expected births having to equal the total of the observed births In both cases the χ^2 table shows that P is less than 0 01 The differences from the uniformity that we presumed ought to be present are therefore more than would be ascribed to chance, and we conclude that neither live nor stillbirths are distributed evenly over the twenty four hours in these records The differences of the live births from uniformity are more striking than those of the stillbirths, for they show a systematic excess during the hours between 9 P M and 12 noon and a deficiency between 12 noon and 9 P M , with the stillbirths there is some change of sign from one period to another which makes the differences from uniformity less clearly marked—perhaps due to the relatively small number of observations Inspection of these differences themselves adds considerably to the information provided by χ^2 The latter value tells us that the differences are not likely to be due to chance , the differences themselves show in what way departure from uniformity is taking place, and may suggest interpretations of that departure

INTERPRETATION OF THE ASSOCIATIONS FOUND

It must be fully realised that χ^2 gives no evidence whatever of the *meaning* of the associations found For instance in Table VIII the value of χ^2 was such that we concluded that the intelligence and the state of nutrition of a group of children were not independent The interpretation of that association is quite another matter We cannot say offhand that the state of nutrition *affected* the level of intelligence Possibly those children who fell in the group with low intelligence had more instances of subnormal nutrition because intelligence is an inherited characteristic and parents of low intelligence may feed their children inefficiently Similarly one measles serum may have "prevented" measles to a greater extent than another not because of its superior efficiency but because the children to whom it was administered had in fact been less exposed to risk of infection. We need to be satisfied that the children were effectively equivalent in other relevant respects The value of the χ^2 test is that it prevents us from unnecessarily seeking for an explanation of, or relying upon, an "association" which may quite easily have arisen by chance But if the association is not likely to have arisen by chance we are not thereby exonerated from considering different hypotheses to account for it If we use some form of treatment on mild cases and compare the fatality experienced by those cases with that shown by severe cases not given that treatment, the χ^2 value will certainly show that there is an association between treatment and fatality But clearly that association between treatment and fatality is only an indirect one We should have reached just the same result if our treatment were quite valueless, for we are not comparing like with like and have merely shown that mild cases die less frequently than severe cases Having applied the sampling test we must always consider with care the possible causes to which the association may be due

It must be observed also that the value of χ^2 does not measure the *strength* of the association between two factors but only whether they are associated at all in the observations under study Given sufficiently large numbers of observations the test will show that two factors are associated even though the degree of relationship may be very small

THE "FOURFOLD" TABLE

With what is known as a fourfold table—i.e , one with four groups in it—χ^2 may be calculated by means of the expected numbers, in the way previously illustrated, or alternatively from the formula

$$\chi^2 = \frac{(ad-bc)^2\,(a+b+c+d)}{(a+b)\,(c+d)\,(a+c)\,(b+d)},$$

where a, b, c, and d are the numbers falling in the groups and the additions are the totals in the margins, as in the Table below

—	Number of individuals—		Total
	Inoculated	Not inoculated	
Number of individuals attacked	*a*	*c*	*a+c*
Number of individuals not attacked	*b*	*d*	*b+d*
Total	*a+b*	*c+d*	*a+b+c+d*

n in this case is only 1 since when one expected value has been found the remainder can be found by subtraction The χ^2 table is therefore consulted with $n=1$ and the value of χ^2 found from the observations

If the numbers involved are small the value of χ^2 will be more accurately given by the formula:

$$\chi^2 = \frac{\left(ad - bc - \tfrac{1}{2}(a + b + c + d)\right)^2 (a+b+c+d)}{(a+b)(c+d)(a+c)(b+d)}$$

where *ad* is the bigger of the two cross products (a correction due to F. Yates).

For instance suppose the Table is as follows:—

—	Inoculated	Not inoculated	Total
Attacked	10	65	75
Not attacked	30	95	125
Total	40	160	200

The larger cross product is 30 × 95. For χ^2 we therefore have

$$\frac{\left(95 \times 30 - 10 \times 65 - \tfrac{1}{2}(200)\right)^2 \times 200}{40 \times 160 \times 75 \times 125}$$

and $\chi^2 = 2·7$. For $n = 1$ and $\chi^2 = 2·7$ P is 0·10, so that the difference between the inoculated and uninoculated is not more than might be expected to occur by chance (10 times in 100 tests would we reach so large a difference by chance). Without the correction $\chi^2 = 3·33$ and P is 0·07, which rather exaggerates the association. This is the value we should also reach if we made the calculation by means of the expected values. In this case we should argue that according to these figures the chance of being attacked is 75/200. The chance of being inoculated is 40/200. The chance of being an inoculated *and* an attacked person if the two characteristics are independent (our testing hypothesis) is then (75/200 × 40/200). This is the chance for each of the 200 individuals observed. Therefore the number we should expect to see in the inoculated attacked cell on this hypothesis of independence is 200 times the probability or 200 (75/200 × 40/200) = 15. It will be noted that the actual number (10) is rather less than the expected number. The difference between these observed and expected values is 5, its square is 25, and dividing by the expected number the contribution of this cell to χ^2 is 1·66. The other expected values can be similarly calculated (or by subtraction from the marginal totals) and their contributions to χ^2 computed. χ^2 then equals 1·66 + 1·00 + 0·42 + 0·25 = 3·33 as above.

These results could, of course, be equally well tested by means of the formula for the standard error of the difference of two proportions. 25 per cent of the inoculated and 40·6 per cent of the uninoculated were attacked, a difference of 15·6 per cent. The standard error of this difference is, as previously shown,

$$\sqrt{\frac{37·5 \times 62·5}{40} + \frac{37·5 \times 62·5}{160}} = 8·6$$

(where 37·5 is the percentage attacked in the total group). The difference is not twice its standard error and therefore cannot be regarded as an unlikely event to occur by chance.

THE ADDITIVE CHARACTERISTIC OF χ^2

One further characteristic of χ^2 is useful in practice. Suppose we had three such tables as the above showing the incidence of attacks upon different groups of inoculated and uninoculated persons, observed, say, in different places, and each table suggests an advantage to the inoculated but in no case by more than could fairly easily have arisen by chance—e.g., the χ^2 values are 2·0, 2·5, and 3·0, and with n equal to 1 in each case, the P's are 0·157, 0·114, and 0·083. The systematic advantage of the inoculated suggests that some protection is conferred by inoculation. We can test this uniformity of result, whether taken together these tables show a "significant" difference between the inoculated and uninoculated, by taking the sum of the χ^2 values and entering the χ^2 table again with this sum and the sum of the n values—namely, $\chi^2 = 2·0 + 2·5 + 3·0 = 7·5$ and $n = 3$. P in this case is slightly larger than 0·05, so that we must still conclude that the three sets of differences, though very suggestive, are not quite beyond what might fairly frequently arise by chance in samples of the size observed.

Finally it must be noted that χ^2 must always be calculated from the *absolute* observed and expected numbers and never from percentages or any other proportions.

SUMMARY

The χ^2 test is particularly useful for testing the presence or absence of association between characteristics which cannot be quantitatively expressed. It is not a measure of the strength of an association, though inspection of the departure of the observed values from those expected on the no-association hypothesis will often give some indication, though not a precise numerical measure, of that degree. As with all tests of significance the conclusion that a difference has occurred which is not likely to be due to chance does not exonerate the worker from considering closely the various ways in which such a difference may have arisen. In other words, a difference due to one special factor is not a corollary of the conclusion that a difference is not due to chance. There are a number of ways in which the value of χ^2 can be calculated, some speedier than others. An alternative method is given for fourfold tables and a correction in such instances for small samples. The calculation of χ^2 must always be based upon the absolute numbers. In this discussion the mathematical development of the test and the foundation of the table by means of which the value of χ^2 is interpreted in terms of a probability have been ignored. The test can be applied intelligently without that knowledge, provided the rules for calculation of the values of χ^2 and n are followed, and the usual precautions taken in interpreting a difference observed.

ALVARENGA PRIZE.—The College of Physicians of Philadelphia will award the Alvarenga prize, amounting this year to $200, on July 14th to the author of the best essay submitted on any branch of *medicine*. Essays must be original unpublished contributions and should be typewritten in standard English, or be accompanied by an English translation. Each essay must be sent without signature but must be plainly marked with a motto and be accompanied by a sealed envelope having on the outside the motto of the paper and within the name and address of the author. They must reach the secretary of the college, 19 South 22nd-street, Philadelphia, before May 1st.

The Alvarenga prize for 1936 has been awarded to Dr. Harry Eagle, passed assistant surgeon, United States Public Health Service, who is at present stationed at the Johns Hopkins Hospital. Dr. Eagle's essay dealt with the present status of the blood coagulation problem.

SPECIAL ARTICLES

USE OF CERTAIN COAL-TAR NAPHTHA DISTILLATES FOR THE DESTRUCTION OF BED-BUGS*

By S A Ashmore, B Sc , A I C
GOVERNMENT LABORATORY AND
A W McKenny Hughes, D I C , F R E S
BRITISH MUSEUM (NATURAL HISTORY)

A number of experiments both in the laboratory and the field have been carried out which show that the vapour of certain coal tar naphtha distillates is lethal to the bed bug (*Cimex lectularius* Linn) Toxicity experiments have also been carried out by Dr G R Cameron at University College Hospital medical school, London, and these tests have shown that animals kept for prolonged periods in an atmosphere saturated with the vapour have not been injuriously affected in any way and afford some considerable assurance that no danger to man from this cause is to be apprehended

A method for applying these naphtha distillates to the disinfestation of houses has been developed and consists essentially in spraying the walls and ceilings of rooms which have previously been made gas tight by any of the usual methods of sealing Special attention is given to likely harbourages such as skirting boards and architraves, a high pressure hand syringe being used for spraying such harbourages Gas masks with a suitable filter are worn during the process

To ensure satisfactory results it is important that sufficient vapour concentration be maintained and for this purpose fumigation should not be begun at a temperature of less than 60° F It is an advantage to work as much above this temperature as is practicable

The quantity of naphtha used in the experiments is on the basis of 1 gallon per 750 cubic feet of room space The rooms are kept sealed for 18–24 hours and at the end of this time are rapidly ventilated by opening doors, windows, fireplaces, &c The vapour clears very quickly and it is possible to enter a room after a few minutes' ventilation without experiencing any discomfort It has moreover been shown that there is no tendency for a concentration of vapour to "build up" if after ventilation the doors and windows are again closed for several hours

The desirability of a high initial temperature is emphasised and only in very hot weather with air temperatures of 70°–80° F should preheating of houses be dispensed with In the experiments a very effective paraffin stove working on the Primus principle has been used, but in any case sufficient time must be given to warm walls, ceilings, &c , thoroughly Owing to the inflammable nature of the naphtha, fires or other sources of heat must be extinguished and if portable removed from the rooms before fumigation is started and smoking and the use of naked lights must be prohibited whilst the naphtha is being handled in any way

The experiments indicate that after a house has been warmed it is advisable in most instances to spray the roof space before the rooms are treated

Successful results have been obtained in the disinfestation of upwards of 200 houses and flats of varied constructional detail Failure has been reported in a few cases but this we think has been incidental to the development of a suitable technique for applying the naphtha After fumigation for 24 hours dead bugs will sometimes be found on the floors, but usually they will be found dead in their customary hiding places—e g , behind skirting boards, picture rails, &c

The naphtha used is derived by the distillation of coal tar and consists of a complex mixture of aromatic hydrocarbons and associated bodies, and the constituent or mixture of constituents which is toxic to the bed bug is not known The following specification has been drafted to govern the supply of coal tar naphtha as used in these experiments

SPECIFICATION FOR HEAVY COAL-TAR NAPHTHA

1 *Colour* —Shall not be darker than a freshly prepared *solution of 1 0 ml of N/10 iodine in 1000 ml of distilled* water

2 *Specific gravity* —Not less than 0 835 and not greater than 0 910

3 *Water* —Shall be free from water and other visible impurities at 15 5° C

4 *Distillation range* (method as defined in B S I specification No 479 for coal tar naphthas) —Up to 160° C not more than 5 ml Up to 190° C not less than 90 ml

5 *Flash point (Abel)* —Not less than 105° F

6 *Tar acids and tar bases* —Not more than 0 25 per cent of tar acids and 0 25 per cent of tar bases

Further research into various aspects of the question of the use of heavy coal tar naphthas for the destruction of bed-bugs is in progress and new methods for more effective application are in course of development

As will be seen from these preliminary notes, the use of coal tar distillates for the destruction of the bed bug is still in the experimental stage, but the results so far achieved are promising and indicate that further research on these lines may produce valuable results

As was to be anticipated, failures have occurred—not, however, owing to defects in heavy naphtha as a toxic agent for destruction of bed bugs but owing to defects in the methods of employing it for that purpose If, therefore, those responsible for the management of house property adopt this method of treatment for eradication of bed bugs, *it is important* that they should realise that the technique of fumigation with heavy naphtha is still the subject of test and research and that the cause of any failure is first to be sought in the method used. In the event of failure, the circumstances of the particular case should be carefully investigated, especially in regard to the temperature at the time of fumigation, to the sealing of the premises, and to the distribution of the vapour

MEDICINE AND THE LAW

Incomplete Tonsillectomy

An instructive case in the West London County Court last week arose out of a complaint that a surgeon had been negligent in the removal of tonsils A five year old boy living in Fulham was taken by his parents last July to the Victoria Hospital for Children in Tite-street Chelsea The parents alleged that the surgeon who operated instead of taking out the tonsils merely clipped off a small piece and left the major part in the throat The tonsils it was said were in a septic condition proper removal would have cured the child the incomplete operation opened up the part which remained to infection and a serious illness of nine days followed the tonsils being ultimately removed by the dissection method at the Princess Beatrice Hospital nearly four months later The medical attendant who saw the child a few days after the first operation gave evidence that the tonsils were then still there and were inflamed Asked if he suggested that it was possible for a surgeon to remove the tonsil completely in every case, he replied it is possible in every case The defendant surgeon stated that he had performed nearly 18 000 such operations The child had very large tonsils which almost met He used the guillotine method The part which he removed was so big that he did not think anything had been left he saw no remnant Judge Hargreaves decided in favour of the surgeon A medical practitioner does not contract to perform a cure; he merely undertakes to use such reasonable care and skill as will be expected of a man of his professional standing Was it negligence to use the guillotine method? The defendant, who demonstrated this method to the judge with the aid of the instrument said that it obtained complete removal in almost every case and it was a recognised method used in almost every clinic and hospital in London The judge evidently accepted the opinion that the method was proper Whether or no the evidence for the plaintiff conveyed the impression that tonsillectomy was a simple operation wherein no competent surgeon could ever fail to effect a complete removal nothing in the judgment supports the view that failure to effect complete removal must necessarily amount to negligence and must involve payment of damages

A Lapse of Memory

An incident discussed at a recent inquest in Chester—the omission to order an ambulance—was explained by a medical witness as due to the overworking of doctors at the time Their surgeries were crowded The coroner agreed that the doctors had been very busy indeed they had been almost run off their legs and allowance must be made in the circumstances The inquest concerned the death of a man aged 78 in an ambulance on the way to hospital The patient fell ill but refused to have a doctor His landlady however sent for the doctor one Saturday The doctor said he was so busy that he might not be able to come till the Monday As he did not come by the Tuesday she called again and the doctor's assistant visited the patient on the Wednesday At a second visit on the following Saturday the assistant said the patient ought to be removed to hospital The landlady went to the doctor that evening for a note for the hospital. She waited an hour for the doctor to come in from visiting patients but failed to see him Her son eventually got the note for the hospital but no ambulance arrived Next day the patient got up and dressed to be ready to go to hospital but still no ambulance arrived. The landlady's son went to the doctor's surgery and found that the ambulance had never been ordered It arrived at last at 10 30 A.M The patient apparently walked downstairs to the ambulance He died before the hospital was reached, from cardiac failure due to bronchial pneumonia The coroner naturally felt bound to investigate the omission to order the ambulance and also the question of the patient's fitness to be moved. He recorded a verdict in accordance with the medical evidence observing that the omission was unfortunate, but adding that these failings of memory did sometimes happen and indeed in moments of great pressure could easily occur

VIENNA

(FROM OUR OWN CORRESPONDENT)

ALARMING DECREASE IN THE FERTILITY OF VIENNA FAMILIES

According to the statistical report of the Official Bureau of Health of Vienna the deaths each month outnumber the births by over a thousand. This deplorable condition is explained by the fact that out of the marriages of the ten years 1924–33 no less than 53 per cent. have so far been childless and even in the remainder the number of children has decreased In 1890–1903 only 10 per cent of the married couples were childless there were 22 5 per cent in 1904–13 and in the upheavals of 1914–23 the figure went up to 30 per cent Again in 1890–1903 more than 30 per cent of the parents had three or more children in 1904–13 there were only 21 per cent while in 1914–23 only 10 per cent. had two or more offspring and in the last decade this figure fell to 3 per cent The one child family has not suffered such serious changes for in 1890 24 per cent of the couples had only one child in 1914–23 the figure stood at 37 per cent and now it is 35 per cent Two child families prevailed in the period 1890–1903 in about 25 per cent of all families, but since 1924 only in 9 per cent

The picture is similar when the number of school children in Vienna is considered. Last year the total number of schools in this city has gone down by 205 to 3585 the number of pupils was 123 061 (a drop of 8331) in the public schools and 10 313 (400 less) in private schools These figures apply only to school-children aged 6–14 of whom in all we have now 24 000 less than four years ago Another result of the serious decrease of young people in the population is the lack of juvenile labourers apprentices clerks and shop assistants in the age group 16–25 According to census figures juvenile labourers amounted to 44 6 per cent in 1910 and dropped to 24 per cent in 1934 The situation is even graver amongst the commercial and office employees where the figure dropped from 13 per cent to 5 7 per cent. Of course this is not due only to the decrease in young people but also to the economic crisis in this country; it is however a characteristic feature of the increase in the elderly population But if economic recovery should take place in a couple of years or so there will be a great dearth of the necessary juveniles

BLOOD PRESSURE PULSE AND RESPIRATION RATE IN CHILDREN

Speaking before a recent meeting of the Vienna College of Physicians Dr Helmreich described an investigation into various normal readings in children of different ages A normal pulse rate is 120 in the first year of life, it is 112 in the second year, 107 in the third, 99 in the fifth, 90 in the eighth, and then it drops by 2 beats a minute for every year to the fifteenth when 76 is about the normal average, decreasing to 72 in the adult The individual variation in these averages is much greater among children than among adults Exercise increases the pulse rate in children much less than in adults A useful test can be applied by making them sit up from a prone position ten times This has been found to increase, on an average, the pulse rate of a four-year old child by 9 beats per minute, by 7 beats at six, 12 beats at eight, 16 beats at twelve, and 18 beats at fifteen In adults this exercise gives an increase of about 12 beats

The respiration rate of a healthy baby of one year is on an average 30 per minute, it is 26 at five, 20 at eight, 18 at ten, and 16–18 in the adult Normal respiration is more easily disturbed in infants than in adults The effect of exercise also varies at different ages, instances being noted where an increase of 8 per minute took place, while other children, owing to deep breathing, showed a decrease of 4 Systematic observations of the systolic blood pressure shows it to stand at about 84 mm Hg up to the sixth year, it is 90 mm at ten, 100 mm. at twelve, and reaches the adult figure of 120 at fifteen Similarly the diastolic pressure of children up to ten is about 62 mm, 70 mm at fifteen, and about 80 mm in the adult Moderate exercise increases the blood pressure of the adult by 20 mm, intensive activity by 40–50 mm This increase is however very irregular in children, so that no normal or average values can be stated

THE FIRST RADIOTHERAPIST

Forty years ago, on Jan 15th, 1897, Dr (now Prof) Leopold Freund, who had taken up here the study of Röntgen's new discovery, demonstrated before the Vienna Medical Society the first patient ever treated by X rays, and he thus inaugurated X ray therapy Freund's patient and exact observations have therefore called into existence a therapeutic procedure which is no less important than the diagnostic value of X rays, and which has become an indispensable part of medicine This first patient had a hairy mole of enormous extent, and it is remarkable that even in this first case Dr Freund used the method of protracted fractionated irradiation, which has survived every other method that has been brought forward in the 40 years of its existence Prof Freund's second therapeutic achievement was the application of X rays in tuberculosis, at first to the skin, then to bones and joints, and finally to the testes In parenthesis it may be stated that Coutard's method of radiotherapy now used extensively for tumours of the respiratory tract is based on Freund's original principle The Vienna Medical Society as well as the Austrian Roentgen Society commemorated the historic day by special festival meetings, and Prof Freund was the recipient of numerous honours from all parts of the world—except from Germany The reasons are obvious—he does not belong to the "German" race

MORTALITY STATISTICS FOR 1935

From an official report of the statistical office we learn that of the deaths in Austria 17 per cent males and 21 per cent females were from diseases of the circulatory organs, 12 3 per cent and 14 5 per cent from neoplasms, 9 6 per cent and 7 9 per cent from tuberculosis, and 8 6 per cent and 8 3 per cent from pneumonia Taking 100,000 of the population as a unit, we find that the mortality has gone down nearly in every respect For the circulatory system it fell from 234 four years ago to 231 per 100,000 living, for tuberculosis in males it fell from 141 5 to 128 5, in females from 100 8 to 93 4 Even the suicides show a decrease, 59 3 males falling to 53 9, and 25 8 females to 24 3 Only the deaths from cancer show an increase 164 1 against the 157 3 of 1931, in males only

CONTRIBUTORY SCHEMES

SINCE the opening of the new premises of the Royal Empire Society in Northumberland-avenue at the end of last year there has been a remarkable development of its numerous activities Among them is the formation of a group of members specially concerned with social services On Feb 18th Sir Francis Morris presided over a meeting when Mr F B Elliot, the general secretary of the Hospital Saving Association, gave an account of the development of contributory schemes By the establishment of an organisation independent of the hospitals, though working closely with them, the objections of the medical profession to anything in the nature of a contract had been overcome The funds raised through these organisations were an increasingly important factor in the finances of voluntary hospitals and would be even more so if the example of employers in Sheffield in adding one penny a week to the contributions of their employees were followed in other parts of the country Mr Elliot claimed that by providing a common voucher for council and voluntary hospitals the contributory schemes were assisting in the coördination of hospital services In the thirteen thousand groups of the Hospital Saving Association there is a large body of voluntary service through which is being developed a new interest in and understanding of hospital work Mr C E A. Bedwell, house governor of King's College Hospital, speaking as a life fellow of the society, directed attention to the possibility of extending this method of support for the voluntary hospitals to other parts of the British Empire At present the principal example of a flourishing contributory scheme is in the State of New South Wales This is particularly interesting as legalised sweepstakes and other speculative methods of raising money have been tried there and found wanting In four years the Metropolitan Hospitals Fund in Sydney has enrolled over two hundred thousand contributors with an income for the last financial year of over £175,000 showing an increase of £50,000 on the previous year The Minister of Health, the Hon H P FitzSimons, had congratulated the hospital secretaries at this last conference on the way in which they had handled the contribution scheme

---

INTERNATIONAL UNION AGAINST TUBERCULOSIS—At a recent meeting of the executive committee of the International Union against Tuberculosis in Paris, it was agreed that the tenth conference (which should have taken place in Lisbon in last September) should take place in September, 1937, if possible in Lisbon The final decision, however will not be taken till the end of April or the beginning of May It was also decided that the eleventh conference of the Union should meet in 1939 instead of 1938, in Berlin The members of the committee expressed their gratitude to the Italian Government for having placed at their disposal six scholarships at the Carlo Forlanini Institute in Rome

POWICK HOSPITAL, WORCESTER—On Feb 15th a new treatment centre was opened at this mental hospital The centre has cost £6000 and includes an operating theatre, an X ray department, and a dental room The proportion of recoveries has increased from an average of 25 per cent for the five years ended 1925 to 42 6 per cent for the five years ended 1935

FROM A RUSTICATING PATHOLOGIST *

I

THE paper this morning tells me that my old tutor is dead, and it makes me think again of all I owe to the personalities that I have had the luck to be in contact with. I was I think the only man reading science in college and there was no science fellow to guide my studies and I suppose I was assigned to Phelps because he was a political economist with a special interest in the outcast and needy and a distinguished chairman of the Oxford Board of Guardians He must have been nearing 50 at the time, had an impressive beard, wore a straw hat through the winter and lunched daily off a rice pudding He told me that of course he knew nothing about the available lectures and classes in natural science and that I had better go to the museum to a man called Burdon Sanderson and ask him what I had better do meanwhile would I write him an essay on—I forget what but it would be party government or is the good always the beautiful? or something of that sort—and bring it to him next Tuesday night at 9 o clock. And so for several years I spent an hour or an hour and a half with him each week reading him the essays of a very crude boy and listening to his talk talking was his specialty in life and he was very good at it, and often enough my first few sentences would fire him off for the rest of the evening Once his friend York Powell came across from the House and I sat in the corner and heard such talk as I had never dreamed of. He took me for Sunday walks to Otmoor and over Wytham Hill and round the countryside, never emerging from college till 11 1 A M when everyone was safe in church never smoking in public, and always talking and trying to make me talk on questions which I had never known to exist and which had this only in common that they had nothing whatever to do with natural knowledge indeed, I do not think he had the least idea what science was about or took any interest in it But he was determined that I should not be lost in the horrid purlieus of the laboratories which Council said when suggestions were made to increase the lavatory accommodation in the physiology building already took men away from their colleges too much. He even made me write a prize essay on Raleigh—an essay for a prize I mean it did not get it—and one way and another he gave me one of the finest doses of education I have had from anybody which I remember gratefully when I help myself to brown sugar out of the beautiful little bowl he gave me for a wedding present.

* * *

It would please my senile delight in reminiscence and bore everybody else if I were to go into details about the other teachers who did so much for me—Ray Lankester Burdon Sanderson J S Haldane James Ritchie Gustav Mann—and trying to practise the decorum on which the Rev Lancelot Ridley Phelps always insisted I mention only those who are dead and though it blunts my illustrations say nothing about those from whom I got nothing but knowledge. The men I remember were not necessarily good teachers in the ordinary sense; Lankester was the best lecturer I have ever heard, and Sanderson s lectures on what he called general pathology were frankly unintelligible though I fancy I could understand them now The pleasure and profit of being in contact with these men was in the atmosphere which was about them they emanated a sort of aura, and engendered the same kind of respect—affection seems almost a frivolous word—which instinctively sent up my hand to take my hat off in recent years when I met Karl Pearson in the street Being no psychologist I cannot analyse the aura but I think it depended on the fact that their minds were fixed on things in front which, in matters concerned with natural science are perhaps not very different from things above. They were of course full of learning but learning was to them of value only as a stepping stone to more learning and the lesson which their saintly lives (saintly perhaps only intellectually) preached to us young men was that we ought to do our best to know more about the world we live in before we died. Each in his own way they set us an example which we could not fail to admire even if our day dreams to follow it have come to very little. I have asked a number of men, more or less my contemporaries what chiefly impressed them in their undergraduate days at Cambridge Oxford, Edinburgh University College &c and what they brought away of best value and apart from the cynic who thinks it funny to say nothing they have all told me of personalities among their teachers—not the men of whom a few are scattered among university staffs who are notorious as buffoons or boors or inanities of some sort but the sanctified apostles of the progress of knowledge whom I have been trying to commemorate Men do not seem to remember classes or curricula they remember people

* * *

This gossip is I hope more relevant than it may seem to the teaching of medical students about which there has been so much discussion for at least the last 30 years and fortunately so little action The important thing is the personality of the teacher If he is to command the respect and attention of his students he must of course know his subject and he should know it in the right kind of way that is looking forward. To hand out the present state of knowledge as if it were a system of revealed truth may perhaps get men past jaded examiners but it is a travesty of education of university standard. Truth has several times been defined as that which opens up fresh fields to human curiosity it was indeed the apparent completion of the classical explanation of the world which made physicists question its validity and led to the modern revolution of thought about the constitution of matter The search for truth is a pilgrimage: we do not know where we are going but we know where we are at the moment and we know how we have got there and the impression made by the teachers I remember came from their being manifest pilgrims rather than spectators *Nullius in verba magistri* is a good enough motto in its way but it is palpable nonsense to apply the heuristic method to the whole of undergraduate teaching, and much of the instruction given must depend on authority, while students will listen to the authority of one who has been himself a pilgrim in a way which they will not accord to one who is simply a magnified version of themselves. This is indeed the reason why so much importance is attached in appointing university teachers to their interest in the personal pursuit of knowledge. People sometimes wonder that more stress is not laid on a man's capacity as a teacher by which they probably mean his facility for grouping current truth in rows and columns, and making lists which can be memorised without too much difficulty. We all—teachers and students—find these tricks useful, and a certain handiness in them is not to be despised, but unless the genuine fire is behind them they will leave the student very cold. Phelps had the fire in him—you could see it in his eyes—and if I failed to understand much of what he told me he made me warm.

---

* The fourth and concluding article by "A Rover" in this series will appear in a subsequent issue —ED L.

* * *

Academic faith involves the preservation, collection, and transmission of knowledge, and of the three it is perhaps the first which is apt to be most neglected; a volume of THE LANCET of 50 years ago probably contains about as much that we do not know as the current issues, but they are not I fancy much used for miscellaneous reading partly perhaps because they are big and awkward to handle, while the weekly numbers may be taken in bed—ignoble but pertinent considerations. We cannot have seminaries of sound learning or education of more than second rate quality without scholarship and research—for I cannot any longer evade the use of that word though it has been so mauled in recent years that it becomes sometimes almost repulsive. Teaching needs research, and research so often needs teaching, that the proposals which have recently been made that they should be separated seem deplorably short sighted. The close connexion which has hitherto existed is fully justified on much more than historical grounds though we have now passed away from the time when anyone who wanted to do laboratory work has practically no alternative to getting a teaching appointment. Whole time research as a life's occupation is a new development and we do not know at present how it will work out in the long run. There are of course a certain number of men who have the flair for getting new knowledge and are temperamentally not suited to teach, generally because they are too shy and nervous, and certainly a class of undergraduates never ceases to be rather a terrifying proposition. And there are a few people who can live up to the novelist's idea of the great scientist who lives a solitary and remote life of meditation and experiment, and periodically startles the world with a cure for cancer or a voyage to the moon, or what not. But there are not many of them, and the successful investigator is generally a pretty ordinary kind of man who has a natural liking for mixing with his fellows. Where he differs from them is mainly in his curiosity and his capacity to see unexplained problems where other people will see nothing out of the way. Tea-time gossip once came round to Bayliss, probably soon after his death, and some one said, "Oh, Bayliss would have made a good research out of it if he had been a bus conductor," which always seemed to me to put a great truth very well; one likes to think of that lovable figure punching tickets and talking about it afterwards to the Physiological Society. And as to being professional meditators—well, I have asked a number of my friends who are more or less distinguished, and they one and all confess that they are quite incapable of sitting down and thinking, and that any ideas they may have had just come into their heads. There are too a certain number of investigations, especially those involving experiments, which actually need the whole of a man's working day though not necessarily all of his working days, and there is more of this kind of thing than there used to be because of the more elaborate scale on which inquiries are pitched nowadays—more elaborate that is on the physical side, not on the mental.

* * *

For these reasons a certain amount of whole time research is as essential as it is undoubtedly productive, but it has its drawbacks, and there could easily be too much of it. One of the most important things to encourage the progress of knowledge is first rate undergraduate teaching by men who have adequate knowledge to transmit the elements of a subject and have themselves a passion to reach out to the things which are in front. The student needs the intangible atmosphere, and at least as much the tangible information which will form the background for any curiosity he may himself develop. There are far too many people nowadays engaged in what they (and other people who ought to know better) are pleased to call Research who are woefully ignorant of the subject within which they are working; some of them actually get doctor's degrees from universities when they would certainly be ploughed in the bachelor's examination in the topic. A man is clearly unfit to engage in medical research without a really good all round knowledge of medicine and para medicine, or to pretend to advance bacteriology without knowing about as much of Topley and Wilson as the authors remember of their own book. And it is a great drawback of too much whole time research that some of the most desirable teachers are withdrawn from the teaching world. Look for example in London at the galaxy of talent and personality which is secluded in the Lister Institute and the National Institute at Hampstead; some of the staffs of these organisations are probably best where they are, but it seems a great pity that the London undergraduate has no chance of sitting under the most learned bacteriologist in the country or—well, perhaps I had better be proper rather than personal and not go into too many details. At any rate, the present position is not the most ideal either for teaching or research.

* * *

So far from deteriorating a man's research, a moderate amount of teaching would in many instances do it good. Just as he should suck up wide knowledge when he is an undergraduate, so he must keep his knowledge wide when he becomes a senior student, and if he spends most of his time at the bottom of his own well he is apt to miss what is going on. As a teacher he cannot neglect it. There is too nothing like teaching for getting one's ideas in order, especially elementary teaching, and the fallacies of traditional arguments are particularly liable to show themselves when they are being expounded in a milk and water form; the innocent questions of babes and sucklings, as yet untrammelled by convention, are also often illuminating and disconcerting in reminding one of what one does not but ought to know. Now this is just what the investigator needs. His natural curiosity has to be disciplined by circumspection if it is to be productive. Unsolved problems are as the hairs of his head, but the only ones worth attending to are those which can be posed in a soluble shape half the difficulty of finding the answer is overcome when the question has been asked in a proper form. He has to learn to be content to answer questions each one of which is in itself a small thing The pith of gaining new knowledge is indeed simplification which is the pith of teaching too Hence it is natural that the two go so easily together The researcher too has much to gain from the give and take of his colleagues in an active teaching school and when the time comes as it surely will, that his productive capacity is in abeyance for a while he can occupy himself with other things and feel that he has earned a good night s sleep What a miserable time the pure researcher must have when he feels that he is not justifying his salary and how much bad work such a mood may lead to! And if his fire has died out, as it sometimes will, what is he to turn to? For a restricted life of research or perhaps I should say a life of restricted research is no training at all for a teacher No teaching and research have natural affinities with one another and they should not lightly be put asunder apart from the necessities which I have mentioned. What most teaching schools need is funds for maintaining research which are at their own disposal and which they can use in their own way; they would make good use of them.

CORRESPONDENCE

RITUAL PURGATION

To the Editor of THE LANCET

SIR,—Doubtless the interesting amusing stimulating and provocative article by my friend Prof Witts on Ritual Purgation in Modern Medicine will bring a spate of letters to your box. In this iconoclastic lucubration with which I am largely in agreement he pays me the doubtful compliment of quoting me in derision. I would ask is there any physician who has not had the experience of being called to a case of pneumonia on the fourth or fifth day to find the abdomen grievously distended, and to hear that the bowels have not been properly opened since the beginning of the illness and to wonder what is the best thing to do?

I am not unduly influenced by the eloquent persuasiveness of a Metchnikoff or the enthusiasm of an Arbuthnot Lane, but I do think that a loaded colon tends to abdominal distension and is therefore better emptied at the beginning of an illness I admit that ritual stuffing with unwanted foodstuffs is a contributory cause of distension but I must not embark here on a fresh iconoclasm.

I am Sir yours faithfully

F G CHANDLER.

Park-square West N W Feb 22nd.

To the Editor of THE LANCET

SIR,—I was very much interested in Prof Witts s paper on ritual purgation and in his plea for the avoidance of the bed pan whenever possible In this connexion is there any sound reason for insisting on the bed pan for a healthy woman after a normal confinement? There must be few patients who can survive even a short spell of bed pan existence without losing any normal habit of bowel action which they may have had To quote an excellent text book of obstetrics a daily aperient will probably be required whilst the patient is in bed and this is probably a conservative estimate

If we hope by forbidding even the daily use of the commode to avoid strain and such sequelæ as prolapse surely our results do not justify us The perineum is quite as likely to be soiled on the bed pan and where aperients are given stools are more liable to be fluid

It would be interesting to know from what danger we are protecting our patients when we insist in the ritual of bed pan and frequent purgatives for these normal people

I am, Sir yours faithfully

Oxford Feb 23rd V SMALLPEICE

SURGICAL TREATMENT OF CARDIAC ISCHÆMIA

To the Editor of THE LANCET

SIR,—It would indeed have been misleading if cardio-omentopexy had been already performed upon the patients mentioned by Sir Maurice Cassidy in your issue of Feb 20th Such a contingency emphasises the new responsibility imposed upon those to whom such patients come for advice After seeing the cases of cardiac ischæmia treated by omentopexy shown to the clinical section of the Royal Society of Medicine, I find it hard to believe that these patients could be convinced that their improvement was not due to the operation After all it is natural though illogical, that a patient who has had the courage to submit to an operation should credit it with his relief from symptoms Such patients are not likely to stem the spate that Sir Maurice fears It is surely the duty of the physician to guide the flood into the appropriate channels.

If as I assume from his quotation of Lord Dawson s words Sir Maurice holds that recovery from arteriosclerotic heart failure is the result of a compensatory circulation the physician is faced with the delicate problem of balancing the probabilities of the natural development of this circulation against the hazards of assisting nature s methods by operation and Mr O Shaughnessy has shown convincingly that the operation he has devised can do this.

I am Sir yours faithfully

Hull Feb 22nd HAROLD UPCOTT

ARTIFICIAL PNEUMOTHORAX ON STATISTICAL TRIAL

To the Editor of THE LANCET

SIR,—Dr Andrew Morland in his letter in THE LANCET of last week objects to the comparisons made in the inquiry into the value of artificial pneumothorax carried out by the subcommittee of the Joint Tuberculosis Council. His argument is that the control group consisted of patients with a substantially better prognosis when treated conservatively than the A.P group and that therefore no conclusions could justifiably be based upon the relative survival rates Whether that argument in the particular case is just or not is a matter for the authors of the report to discuss But Dr Morland passes from this criticism of the particular to a criticism of the general and says that the investigation raises the whole question of the applicability of statistics to clinical problems That question concerns me closely because I am at present endeavouring to show in your columns how simple statistical methods can be applied with advantage to many clinical problems

I am inclined to agree with Dr Morland that in assessing the value of A.P it may be very difficult *now* to find two equivalent groups of patients, one so treated, the other not, which are the requirements for an effective comparison (the subject was ably discussed by F J Bentley in his report on the L C C experience published in the *Spec Rep Ser med Res Coun*, *Lond* No 215, 1936) But was it *always* so *difficult*? In the early days of the treatment it was certainly not universally applied to all those patients who to day might be regarded as suitable subjects Some clinicians would in those early days have induced an A P where others would not If while the treatment were in that experimental stage, the clinical trials had been efficiently planned and organised, then, I believe, a measure of its value would have been obtained The statistical method (like any other method) must fail if it has to be applied to faulty material, but faulty material is the product of a faulty experiment The time for a test of a new method of treatment is clearly in its early days when opinions upon it differ, and equivalent patients, treated and untreated, are available for study Too often that critical moment is lost and we fall back later upon second best comparisons

Dr Morland says that there is now "a relatively small group of patients in whom pneumothorax is tried without delay as experience has taught us that their prognosis will be much improved thereby" That conclusion is itself statistical even though it is not given numerical expression. It must be based upon a mental, subjective, comparison, of similar types of patients to whom A P T was applied or not applied. The two groups must have existed, the clinician must have been able to define them as of similar type to reach the conclusion, is it too much to believe that if the critical moment had been seized an objective, numerical assessment could have been obtained by suitable statistical methods?

MEDICAL PRIVILEGE

To the Editor of THE LANCET

SIR,—The introduction into the House of Commons of Sir Ernest Graham Little's Bill for the protection of medical practitioners has brought to public notice a very important question—namely, the position of doctors as regards the secrecy of communications with their patients

The Bill was rejected on two main grounds first there was no statement as to whose privilege the privilege claimed should be, and secondly there was no definition of such privilege I think it is very important that the matter should not be lost sight of and that it should be brought up again as soon as possible I should suggest that the new Bill should be settled after careful legal consultation and should provide (1) that the privilege should be the privilege of the patient, and (2) that the patient should have as regards his medical attendant the same privilege as a client has in regard to his solicitor I think this mode of dealing with the matter would get over a considerable amount of difficulty in the way of definition

I am, Sir, yours faithfully,

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR

To the Editor of THE LANCET

SIR,—May I reply through your columns to some of the points raised by Mr Gissane in his friendly criticism of the technique I described for the introduction of a Smith Petersen nail?

Mr Gissane agrees that traction in a Thomas splint should be the routine method of preliminary treatment and can effect accurate reduction When this is so, therefore, it seems a thousand pities to undo this good work by removing the extension and starting all over again with an orthopædic table if an alternative "bed procedure" can be offered, which is satisfactory Accepting the criterion of satisfaction as (1) accuracy of reduction, and (2) maintenance of this reduction until the nail is in position, the bed technique described fulfils these two requirements Accuracy of reduction must, of course, be controlled by radiograms in two planes, and may be confirmed with advantage immediately prior to operation after the spinal anæsthetic has been given Within five minutes of this the guiding wire can be in position, and as no disturbance of the weight extension has taken place, there is no reason to suppose that the simple introduction of a wire can have caused displacement At this stage, however, there is nothing to prevent as close a radiological control as the surgeon desires, given a good portable X ray apparatus, and lateral radiograms could be taken until sufficient experience of cases gives conviction that the instrument does in itself ensure complete control.

In introducing the nail over the wire inserted right through into the head of the femur, I find it difficult to conceive that the head fragment lying in the acetabulum can move Any movement that could occur must surely be on the part of the proximal fragment of neck, and attached femur with it, and the immobility of this is guaranteed by the weight extension supplemented by the wire Maintenance of reduction is thus sustained until the nail is in position

Finally, if the experience of others should prove the same as my own, they will find that the elderly patients have no fear of what is to them a "bedside treatment" compared with a visit to the theatre for an "operation,' where events that may be no worse than tedium for the surgeon and his assistants are no less than an ordeal for the patient

I am, Sir, yours faithfully,

E T BAILEY

St Leonard s Hospital Hoxton street N, Feb 20th

DEATHS IN THE SERVICES

Inspector General JAMES HAMILTON MARTIN D.S O who died at his home in Ealing on Feb 14th in his 96th year was the son of Hamilton Duckworth Martin, of Truro Cornwall He qualified M.R C.S Eng from University College London in 1864 and entered the Royal Navy the following year becoming fleet surgeon in 1884 deputy inspector general of hospitals and fleets in 1894 and finally inspector-general in 1900 He had a varied experience with Sulee pirates in 1872 during the Zulu war of 1879 the Egyptian war of 1882 the Eastern Sudan campaign of 1884 and the operations against the Sultanate of Witu in 1890 He was mentioned many times in dispatches, was twice wounded and was created D S O in 1891 On retirement in 1901 he was awarded a Greenwich Hospital pension

Major CHARLES EDWARD GREY STALKARTT R.A.M C (retd) who died on Feb 18th at Alverstoke, Hants in his 72nd year was son of John Stalkartt of Chupra Bengal He qualified at Edinburgh in 1886 took his M.D in 1890 entered the R.A.M C and rose to the rank of major in 1903 He served in South Africa in 1900 and was placed on retired pay in July 1911 but was recalled to the active list in August 1914 and put in charge of the base depôt medical stores in France In his earlier post graduate days he had been prosector of anatomy in Edinburgh University and he contributed to the R.A.M.C *Journal* notes on necrosis of the femur malignant new growth of the tibia, fracture of the patella, and observations of the superior vena cava.

OBITUARY

ALFRED JOHN WILSON CHAMINGS,
M B Camb F R C.S Eng

ON Feb 21st Mr Chamings died at Worthing at the age of 33 He was surgeon in charge of the ear nose, and throat department at the Princess Beatrice Hospital and consulting laryngologist to the Woolwich War Memorial Hospital.

The only son of Mr H E Chamings, for many years a distinguished official of the London County Council he was educated at Westminster School and went to Cambridge in 1922 where he became a scholar of St. Catherine s In 1925 he entered St George s Hospital where he quickly distinguished himself gaining several coveted surgical prizes before qualifying in 1927 He took his Cambridge degree in 1929 and the fellowship of the Royal College of Surgeons in 1931 After holding three house posts at St. George s he began to specialise, and was rapidly successful in gaining appointments becoming registrar at Golden-square surgeon to the nose and throat department at Paddington Green Children s Hospital and at Princess Elizabeth Hospital and chief assistant at St Thomas s Hospital. In 1932 he became surgeon to the throat department of the Princess Beatrice Hospital and both there and at St Thomas s he soon made a name for himself by his skill, kindliness and conscientiousness Two of his colleagues write that nothing was ever too much trouble to him if it helped his patient He was utterly selfless in his devotion to work, and this in spite of a frame never robust. In 1934 he recovered from a severe streptococcal infection acquired at operation and once more restarted work with all his former enthusiasm He was warned not to overtax himself but his nature was such that he could never relax as long as there was work to do A little over a year ago he was found to have contracted pulmonary tuberculosis, and was given leave of absence from all his hospital appointments But it was all too obvious even then that the chance of recovery was slender Those of his friends and advisers—and they were many—who watched his long illness were deeply impressed by his cheerfulness and fortitude and no less by the devoted care of his parents

LEONARD MOLLOY M D Dubl

Major Leonard Molloy who died in a London nursing home on Feb 19th in his 76th year had spent most of his active life in practice at Blackpool for which he was Member of Parliament in 1922–23 Son of Richard Molloy of Rathgar co Dublin he was educated at Trinity College Dublin graduating in 1882 and taking his medical degree in 1889 after which he went on to higher diplomas As a student he carried off prizes over a wide range of subjects He was resident at Sir P Dun s Hospital and obtained the special certificate of the Rotunda before settling in Blackpool in 1891 There he became hon surgeon to the Victoria Hospital and hon secretary to its medical board as well as visiting consultant to a number of places including Rossall School. He was constant in helping the St. John Ambulance Brigade as surgeon lecturer and examiner was made an hon life member of the Association and a Knight of Grace of the Order of St John of Jerusalem Already major in the Duke of Lancaster's Own Yeomanry he was in France and Belgium from 1914 to 1917 was mentioned in dispatches and awarded the D S O On his return he became chairman of the Blackpool branch of the British Legion and a justice of the peace He wrote not a little in medical papers on unusual cases that he met in practice while keeping up his early interest in biological research For fifteen years he was chairman of the Blackpool musical festival. Major Molloy married in 1922 Ethel Mary daughter of James W Willan solicitor of Todmorden. Latterly he spent the winter at Monte Carlo on the climate of which he wrote a small treatise His recreations were hunting shooting and salmon fishing and he was a member of the Cavalry and 1900 clubs.

PUBLIC HEALTH

THE L C C HOSPITAL SERVICE

ON the eve of the election of a new council opportunity has been taken by the hospitals and medical services committee, of which Mr Somerville Hastings is chairman, to present the outgoing council with some particulars of the development and extension of the hospital service during the past three years A similar report of the previous three years, when Dr Barrie Lambert was chairman of the corresponding committee, was summarised at the time in our columns (1933, 2, 1341) The number of hospitals, including institutions allocated for use as hospitals, is 74—the same as it was three years ago During the period Heatherwood Hospital, Ascot, has come under L C C control, and the South Grove institution has gone over to the public assistance side At the time of their transfer to the Council six years ago many of the hospitals were not of modern standard in structure, staffing, or equipment, and much leeway has been made up, although much remains to be done Structural changes now in execution or prospect are about thrice as extensive as those at the earlier survey While the staff of the hospitals has been greatly augmented the working hours of the nurses have been reduced, and the engagement of women orderlies relieves probationer nurses of domestic duties and allows them more time for training Almoners have been appointed at all the general hospitals

New accommodation to the extent of 996 beds (including that of Heatherwood) has been provided since March, 1934 Further extensions will increase the number of beds by 1834, not including the scheme for a new general hospital of 500 beds in South London New accommodation has been provided for 813 nurses and is in prospect for another 1596 The number of persons required to administer all these hospitals is very large Three central subcommittees meet fortnightly, and there are 62 separate hospital and institution committees, as well as ten assessment subcommittees, with some 440 members in all. Many of these are coöpted, there are 14 coöpted members on the central committee and subcommittees, while the regional committees consist mainly of coöpted members

The total bed accommodation at the general and special hospitals, including institutions allocated for use as hospitals, is as follows

Year Dec 31st	Accommodation in hospitals	Accommodation in public health institutions allocated for use as hospitals			Total accommodation	Total accommodation for the sick.
		Total	Sick	Other		
1930	32 389	9620	*4018*	*5602*	42 009	*36 407*
1931	32 928	8509	*3935*	*4574*	41,437	*36,863*
1932	32,763	8509	*3751*	*4758*	41 272	*36 514*
1933	32 674	8275	*3885*	*4394*	40 949	*36 559*
1934	32 803	7958	*3382*	*4576*	40 761	*36,185*
1935	32 897	6320	*3051*	*3269*	39 217	*35 948*
1936	32 409	5911	*2929*	*2982*	38 320	*35 338*

The drop in the 1936 figure is explained by the fact that beds at the North Eastern Hospital and the Princess Mary's Hospital, Margate, were out of commission owing to reconstruction But for this the figure would be 33,076

Many of the schemes at fever hospitals relate to the provision of isolation accommodation for the purpose of reducing the risk of cross infection, 265 such beds have been provided at five hospitals and work is in progress at four others Isolation accommodation is required for cases of secondary infection, those in which the diagnosis is doubtful on admission, and the uncommon diseases for which a larger ward is not available This accommodation consists of single bedded wards, separated by partly glazed screens, with duty rooms so placed that the nurses can keep the patients under observation Steps are also being taken to provide three receiving rooms in each of the Council's fever hospitals to facilitate the admission of different types of infections

A striking example of how one change leads to another is afforded by the gift of the United Services Fund in 1934 of Heatherwood Hospital, Ascot, for children suffering from surgical tuberculosis and other orthopædic diseases Originally containing 144 beds this hospital has been extended by the addition of another 100 beds As a result Princess Mary's Hospital for Children, Margate, where similar types of case were treated, is no longer required for that purpose, and is being reconstructed as a convalescent home for women, in place of the existing accommodation at St Benedict's Hospital, Tooting This leaves St Benedict's free for chronic sick female patients

Progress has been made in the scheme for providing a complete pathological service, the simpler examinations being carried out in the hospital laboratories, the more technical ones in group laboratories or in the special histological laboratory Last year the Council approved the establishment of a central biochemical laboratory for investigating nutritional diseases The number of examinations has increased from 180,000 in 1931 to nearly 500,000 in 1936, those in the histological laboratory during the same period from 600 to 22,000

Notable in the tuberculosis scheme is the decision of the Council in 1934 not to ask resident patients for contributions towards the cost of their treatment or for the boarding out of their children, in order not to imperil recovery by financial anxiety Where patients are sent to a sanatorium outside London the Council has accepted responsibility for the cost of further treatment, if the need should arise, up to two years from the date of discharge No charge other than amounts due from a benefit society is made for dentures provided for patients under treatment, clothing, boots, and spectacles may also be provided at the cost of the Council. Facilities for occupational treatment of tuberculous patients are being experimentally provided at Archway and Highgate Hospitals

The reallocation of patients and inmates as between public health and public assistance institutions is proceeding, whereas three years ago there were 4700 public assistance cases being cared for in public health institutions, and about 1600 public health cases in public assistance institutions, exchanges effected by the end of 1936 reduced the figures to 1739 and 803 respectively It is satisfactory that on April 1st next only seven institutions will remain unappropriated

Arrangements for the provision of consultants and specialists are being supplemented in the following manner —

Venereal diseases —A consultant for venereal diseases has been appointed under whose care has been placed the unit at St Margaret s Hospital for the treatment of cases of vulvo vaginitis in children

Thoracic surgery —*In order to obtain the best results* in the general hospitals, a thoracic surgery unit has been established at St Mary Abbots Hospital, at which cases requiring the attention of a thoracic surgeon are concentrated as far as possible The staff of thoracic surgeons at this unit comprises one position of honorary chief surgeon and two positions of thoracic surgeon (part time) As from April 1st 1937 a consulting thoracic physician will also be employed at this unit

Rheumatism.—Three consultants for rheumatism cases who formerly acted in an honorary capacity will be added to the staff of consultants and specialists for research into selected cases of rheumatic diseases at St Stephen s Hospital, as from and including April 1st 1937

Radiologists —In view of the increasing amount of X ray work in the general hospitals arrangements are being made for the employment of full time instead of part-time radiologists In the first instance a full time officer will be employed as from and including April 1st 1937 at each of two groups of hospitals one north and the other south of the Thames

Anæsthetists —The fee payable to anæsthetists called in as required under the scheme has been increased Double fees are payable to consulting anæsthetists in connexion with thoracic surgery when visiting the outlying medical tuberculosis hospitals

Emergency visits —Arrangements have been made for the payment of additional remuneration to consultants and specialists for all visits in excess of the routine visits for which they have been engaged. Under the previous arrangements extra remuneration for emergency visits was not paid unless the consultant or specialist concerned was required to attend in emergencies for sessions amounting during any year to the equivalent of one session a week in excess of the number of sessions for which he had been engaged

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 13TH 1937

Notifications —The following cases of infectious disease were notified during the week: Small pox, 0 scarlet-fever 1450; diphtheria, 1212 enteric fever 49; pneumonia (primary or influenzal) 2539 puerperal fever 35; puerperal pyrexia 127; cerebrospinal fever 33 acute poliomyelitis 13 acute polio-encephalitis 1 encephalitis lethargica 8 dysentery 19; ophthalmia neonatorum 87 No case of cholera plague or typhus fever was notified during the week.

Notifications of acute pneumonia in England and Wales were only 53 per cent above expectation in London itself they were 46 per cent. below

The number of cases in the Infectious Hospitals of the London County Council on Feb 10th was 3354 which included Scarlet fever 805 diphtheria 994; measles 32; whooping-cough 588 puerperal fever 21 mothers (plus 14 babies); encephalitis lethargica 283 poliomyelitis 3. At St. Margaret's Hospital there were 16 babies (plus 9 mothers) with ophthalmia neonatorum

Deaths —In 122 great towns including London there was no death from small pox 1 (1) from enteric fever 5 (0) from measles 3 (2) from scarlet fever 39 (10) from whooping-cough 30 (1) from diphtheria 45 (11) from diarrhœa and enteritis under two years, and 697 (50) from influenza The figures in parentheses are those for London itself

Of the 596 deaths from influenza in the great towns of England and Wales outside Greater London the largest totals were reported from Birmingham 63 Manchester 46, Liverpool 36, Sheffield 18 Newcastle-on Tyne 15 Blackpool 14 Bolton and Sunderland each 13 Of these only Birmingham Liverpool and Newcastle showed a rise on the previous week s figure Corresponding figures for Scottish and Irish towns were Edinburgh 19 Glasgow 15 Dublin 31 Belfast 5

Liverpool reported the only death from enteric fever. The fatal cases of whooping-cough were widely scattered over [illegible]4 great towns, mostly in the northern area Bolton reported 3 Leeds Manchester and Newcastle each [illegible] Fatal cases of diphtheria were reported from 21 great towns Manchester 5 Liverpool 4 Leeds 3

The number of stillbirths notified during the week was 274 (corresponding to a rate of 41 per 1000 total births) including 39 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Regency Bill: Total Incapacity of the Sovereign

In the House of Lords on Feb 10th the Regency Bill passed through the committee stage. On Clause 2 (Regency during total incapacity of the Sovereign) Viscount HALIFAX Lord Privy Seal moved in Subsection (1) to leave out the words on the evidence of physicians or otherwise and to insert by evidence which shall include the evidence of physicians. The amendment he said was proposed in accordance with the promise given by the Home Secretary on the report stage in the House of Commons The object was to remove doubts as to the meaning of the clause as it was originally drafted and to make it clear that the evidence on which the persons designated in the Bill would decide whether the Sovereign had become incapable or not must necessarily include the evidence of physicians but might also include other evidence as well —This amendment was agreed to

On Feb 23rd the Bill was read a third time and passed

Maternity Services in Scotland

DOMICILIARY INSTRUCTION

When the Maternity Services (Scotland) Bill was further considered by a Standing Committee of the House of Commons on Feb 10th discussion was resumed on the following new clause moved by Mr GRAHAM KERR:

In every area where there is a recognised medical school the local authority of that area and the Department of Health shall take steps to secure that adequate facilities are made available for the practical domiciliary instruction in midwifery of any person undergoing training with a view to becoming a duly qualified medical practitioner or a certified midwife

He said that there was nothing new in the method of private domiciliary training for students. The object of the new clause was simply to ensure that the existing method of training students would be maintained and if possible improved Child bearing women must be attended by persons who had undergone proper and adequate training For 33 years he had been in the closest relationship with medical students and those who knew them would have no hesitation in trusting them In 1936 the Glasgow Maternity Hospital practice had 4721 mothers attended in their own homes and out of those there was only one death. Any fear that the student might do maternity work before he had enough general experience was entirely unfounded

Mr WESTWOOD said that the clause directly opposed the spirit and intention of the Bill which had become necessary partly because the poorest classes had been unable to obtain skilled professional attendance The proposed new clause might be an honest endeavour to improve the Bill but it was certainly unwise There was no limit to those who could practise midwifery because the clause said that facilities were to be made available for the practical domiciliary instruction of any person undergoing training' Arrangements for domiciliary treatment should only be made with the consent of those who occupied the homes and not by the local authority alone.

He hoped that the Government would resist the proposal

Mr T M COOPER, Lord Advocate, said that it was vital that there should be continuity in the supply of skilled doctors and midwives, but he did not think this new clause was an appropriate measure to achieve that end. He suggested that under the deliberately wide terms of the provisions of the Bill every facility would be given for training, but that the proposal in the new clause approached the question from an unfortunate angle It would involve, if literally read and inexorably applied, something like an intolerable invasion of the liberties of private people, because it would require the local authority and the Department to secure that adequate facilities for domiciliary instruction were made available to any person engaged in training, which was unnecessarily wide

Sir E GRAHAM-LITTLE said that it was essential to keep the general practitioner trained to the best possible extent Even in hospitals which really set out to deal with midwifery the greater part of these cases were outside the hospitals The students were far from being unpopular in the homes of the people they attended and it was quite wrong to suppose that the mortality among the rich was any less than amongst the poor

Mr CASSELLS said he thought that the Committee would be well advised to accept the advice of the Lord Advocate There was no reference at all in this new clause to the opinion of the General Medical Council There had been no attempt whatever by the mover of the clause to explain what was a recognised medical school and there was no definition There was nothing in the clause to suggest that there was to be personal supervision of the medical students

Mr G A MORRISON said that it was rather a serious thing that the authorities who were responsible for training were firmly of the opinion that the present facilities were not adequate For example, he had been sent figures that showed that 68 per cent of the births in maternity hospitals were abnormal and it was surely not advisable to study the normal from the abnormal —Mr MACLEAN said that the figure quoted by Mr Morrison was the strongest argument for not accepting the new clause

Mr GRAHAM KERR said that he did not feel prepared to withdraw the new clause In his view this was a question of safeguarding human life

The new clause was negatived without a division.

A PANEL OF SPECIALISTS

Mr MATHERS moved the following new clause

It shall be lawful for a local authority to appoint a number of registered medical practitioners to form a panel for the purposes of Section 22 of the Midwives (Scotland) Act, 1915, and when such panel is so formed the medical practitioner called to her assistance by a midwife provided by a local authority under Subsection (1) of Section 1 of this Act shall be selected from the panel so formed

The object of the new clause was to ensure that a midwife who found herself faced with some difficulty should be in a position to call in a medical practitioner skilled in midwifery Figures had been supplied to him by the Glasgow Corporation in support of the contention that the medical practitioner called upon often did not make a point of practising midwifery In Glasgow during 1935 out of 544 medical practitioners whose practice included service under the National Health Insurance Act, 144 did no midwifery, 166 attended 1–5 cases, 82 attended 6–10 cases, 86 attended 11–20 cases, and 66 attended over 20 cases in the year Specialism, however, would not be possible in country districts where practitioners were few, and that was why the clause was made optional. In Glasgow in 1933–35 medical help was called in by midwives in 31–33 per cent of the total births That proved the necessity for providing that a midwife who found herself faced with a difficulty in a confinement should be able to call to her aid a specially qualified doctor at the earliest moment He understood that the proposal had been approved in principle by the Association of Counties and Cities in Scotland and by the Scottish branch of the Society of Medical Officers of Health

Mr ELLIOT said the difficulties in accepting this clause were greater than Mr Mathers realised It could not be complete unless penal provisions were incorporated, and the mere suggestion should make them look at the proposal very seriously The keeping of any medical register was a matter which was carefully safeguarded by the General Medical Council, but under this new clause local authorities would have power not merely to keep a register but to strike people off it, a power with which they had never before been entrusted. Under National Health Insurance even the local authority that was actually administering the benefit had no power to strike a doctor off the panel That could only be done after a special inquiry and a recommendation to the Minister It would be very paradoxical for the Bill to subject a person to severe penalties for having obeyed a call from a midwife that might be very reasonable in the circumstances He hoped that having raised the discussion Mr Mathers would not press the new clause

Mr WESTWOOD suggested that the difficulty about penalties could be avoided if the word " shall " was changed to " may "—Mr CASSELLS said the last proposal would render the clause completely abortive, because there was no doubt that it would be a local midwife who would be called in and should know herself who was the properly skilled medical practitioner to call in He hoped that the Secretary of State for Scotland would be able to bring in a new clause on the Report stage which to a material extent would meet their point

Mr ELLIOT said it was the desire of the Committee that in some way or other knowledge should be available to the midwife about those who were practising midwifery, and Mr Westwood had suggested that some voluntary list might meet the position He himself thought that the local medical practitioners would be able to give better information than anyone else, and such a list could be made available to the midwife These were two reasonable suggestions, but he did not think they should be backed by a penal clause which would put them in great difficulties of drafting

Mr MATHERS asked leave to withdraw the new clause on the understanding that before the Report stage the matter would be further looked into

The Committee stage was concluded and the Bill was ordered to be reported to the House

Sale of Methylated Spirits

In the House of Commons on Feb 17th Miss HORSBRUGH asked for leave to bring in a Bill to control the sale in Scotland of methylated spirits and of methylated spirits in admixture, and for other purposes connected therewith She said that the main provisions of the Bill were based on an enactment by the Parliament of Northern Ireland which had proved satisfactory in dealing with this particular evil Retailers of methylated spirits had to obtain a yearly Customs and Excise licence It was proposed in this Bill that certain further conditions should be attached to the granting of a licence, such as the registration of the applicants with the local authority, the keeping of a record of sales, and the selling only on receipt of an order signed by the purchaser stating the purchaser's address and the purpose for which the spirits were required The measure was not a party one, it had support from different parts of the House She believed it had also the approval of a very large section of public opinion in Scotland With the minimum of inconvenience to those who sold mineralised methylated spirits for legitimate purposes it should be possible to provide a means in Scotland of combating a real menace to the mental moral and physical welfare of the people

Leave to bring in the Bill was granted, and the Bill was read a first time

Special Areas Bill

The Children s Minimum Council which is affiliated with many educational and welfare associations has submitted a memorandum on the Special Areas Bill to the Prime Minister The Council recognises that the primary purpose to which the Bill must be directed is the restoration of prosperity and purchasing power in the areas themselves But it believes that the Government should include in the Bill measures which will protect the health of the mothers and children from the worst effects of long continued poverty and unemployment It considers that the national campaign for a Fitter Britain will become a mockery if the children in distressed areas are denied the food they need for health and growth. The memorandum quotes tables showing that as the number of children in the family increases, the amount of money available for food per head progressively decreases The Council considers that the present distribution of free milk and meals to school-children and free milk to expectant mothers is woefully inadequate and recommends, inter alia, (1) the supply of free milk to children in public elementary schools and to scholarship children in secondary schools (2) the supply of free school meals to children belonging to families where the amount available for food falls below a scale to be determined by the Ministry of Health; (3) the supply of free boots to school-children in such families and (4) the supply of free milk to expectant and nursing mothers and children under school age in such families.

Hospital Provision in Malta

On Feb 22nd the House of Commons went into Committee of Supply on a Supplementary Estimate for Colonial and Middle Eastern Services

Mr ORMSBY GORE, Secretary of State for the Colonies said that the vote was for the money spent at the time of the Italo-Abyssinian war on improved civilian defences The Government had to send out quickly to Malta anti-gas respirators for the civilian population They had to establish an anti-gas school and train people in passive defence in case an attack had taken place during the sanctions period There were also special arrangements which had to be made involving the expenditure of money for the preparation of hospitals in case of attack

The vote was agreed to

Veterinary Education

Mr W S MORRISON Minister of Agriculture said that a sum of £750 for grants in aid of annual expenditure in agricultural colleges and institutes was for the maintenance of the Veterinary College pending a detailed scheme of veterinary education The additional sum of £18,300 for diseases of animals included £10 000 compensation for foot-and mouth disease An increase in the cattle slaughtered under the Tuberculosis Orders was due to the increasing vigilance of the local authorities and farmers Animals were also being condemned at an earlier age when they were normally more valuable The £600 provided for research work under the Diseases of Fish Bill was to pay a man to test fish to see if they were suffering from furunculosis or not

Replying to Mr SHORT he said that Sir Frederick Hobday had retired from the Royal Veterinary College on account of age His great services had been fully appreciated

The vote was agreed to

The Deaf Children (School Attendance) Bill passed through committee

In the House of Lords on Feb 22nd a Bill presented by Viscount GAGE to amend the description of the persons with whom arrangements may be made under the National Health Insurance Act, 1936 for the dispensing of medicines was read a first time

QUESTION TIME

THURSDAY FEB 18TH

Danger to Children of Inflammable Toys

Mr MATHERS asked the Home Secretary whether his attention had been called to recent cases of death through fire caused by the accidental ignition of children s toys made of celluloid and whether he proposed to take action to prevent such articles being exposed for sale

Mr ROLAND ROBINSON asked the Home Secretary how many accidents fatal or otherwise to children occurred in each of the last three years through the use of celluloid toys and whether he would consider the practicability of preventing the sale of inflammable toys —Sir JOHN SIMON replied I have no statistics on the point but accidents of this kind have been brought to the notice of the Home Office from time to time I am afraid that the practical difficulties in the way of controlling the sale of celluloid toys by means of legislation would be very great

Eggs

Brigadier-General CLIFTON BROWN asked the Minister of Health whether he would strengthen the present legislation under the Food and Drugs Act against the sale of dirty or stale eggs —Sir KINGSLEY WOOD replied I will bear in mind the suggestion of my hon friend but I doubt whether the object he desires could be attained by an amendment of the Food and Drugs (Adulteration) Act

Brigadier General CLIFTON BROWN asked the Minister of Health whether he was aware that imported liquid egg juice was used in cakes, buns &c and whether any of the tins that come into this country were opened and subjected to any medical analysis —Sir KINGSLEY WOOD replied: I am aware that imported liquid eggs are used by bakers and confectioners In common with other imported articles of food they are subject to examination at the port of entry and such examinations are I understand, made from time to time A number of special bacteriological examinations of liquid eggs have also been made by my department

St John Ambulance Brigade and the Coronation

Sir THOMAS COOK asked the Parliamentary Secretary to the Ministry of Health as representing the First Commissioner of Works, if he would arrange for a site to be available for the purpose of a camp for members of the St. John Ambulance Brigade drawn from the provinces who would be doing duty in the streets on Coronation day —Mr R. S HUDSON replied: My noble friend regrets that he is unable to entertain this request

FRIDAY FEB 19TH

Diphtheria at Poole

Mr GROVES asked the Minister of Health how many cases of diphtheria had been notified in children at Poole who had at any time received one or more inoculations against diphtheria; and whether any of them were fatal.—Sir KINGSLEY WOOD replied: According to the information furnished by the local authority five such cases have been notified and none of them was fatal

MONDAY FEB 22ND

Cambridge Scientists Anti War Group and Air Raid Precautions

Mr PARKER asked the Home Secretary (1) whether he would make an investigation into the observations of the Cambridge scientists as the result of their examination of recommendations put forward by the Air Raids Precautions Department of the Home Office and (2) whether he would cause to be published the full scientific evidence on which the proposals for the gas proofing of rooms in private houses had been based —Mr GEOFFREY LLOYD Under Secretary Home Office replied: I presume the hon Member refers to the Cambridge Scientists Anti War Group but I would point out that this group must not be confused with the general body of Cambridge scientists, and indeed His Majesty's Government are advised in regard to these matters by the most distinguished scientific experts not only from Cambridge but from Oxford and other universities The observations of the Cambridge Scientists' Anti War Group have been carefully investigated with the result that both the experiments themselves and the deductions made from them have been proved to be open to grave criticism It would not be in the public interest to disclose details of the experiments upon which the Government's plans are based, but, as I said in answer to a previous question, these experiments were conducted with actual war gases liberated under practical conditions, and the measures proposed would be effective in affording a very great measure of protection

Departmental Committee on Night Baking

Mr **Rhys Davies** asked the Home Secretary whether he would give the terms of reference and names of the departmental committee on night baking, and whether he could say when the committee would begin to take evidence —Mr **Geoffrey Lloyd** replied Yes, Sir, the terms of reference of the Committee are "To inquire into the effects likely to ensue to those engaged in the bread baking and flour confectionery industry, and to the public, in the event of the abolition by legislation of the practice of night baking now prevalent in the industry, and to consider and report whether or not such legislation would be desirable" The members are The Right Hon Lord Alness, K.C (Chairman), Mr John Adamson, chartered accountant, of Messrs McClelland, Ker and Co, Mr A W Garrett, Deputy Chief Inspector of Factories, Mr F Marshall, M P, and Sir Assheton Pownall, M P The Committee held a preliminary meeting last week and is taking evidence from the Factory Department to day I understand that arrangements are in train for the associations of employers and workers chiefly concerned to give evidence as soon as practicable Any other bodies of persons desirous of giving evidence should communicate with the Secretary at the Home Office as soon as possible

TUESDAY, FEB 23RD

Employment of Boys in Coal-mines

Mr **Short** asked the Secretary for Mines whether, since boys aged 14 were employed in coal pits on unsuitable work, sometimes with fatal results, he would take steps to prevent the coal owners continuing this undesirable practice —Capt **Crookshank** replied Some occupations are already barred to boys under a certain age, and when the Royal Commission have made their report and new legislation falls to be introduced, the desirability of imposing further limits on the employment of boys will be carefully considered

The Bedeaux System in Arms Factories

Mr **Hardie** asked the Secretary of State for War whether the Bedeaux system or the Taylor system was employed in any of the works or factories receiving contracts from his department —Mr **Duff Cooper** replied I have no precise information regarding the extent to which these systems are employed by war department contractors, but I understand that a number of contractors make use of the Bedeaux system, or some modification of it

Mr **Hardie** asked if the right hon gentleman understood the destruction of the nervous system which took place among workers who were so treated, and if he would take steps now to save the nervous system of persons whom he might require before long, so that he might have these men with completely unbroken nerves instead of men with nerves shattered by a stupid system

No further answer was given

MEDICAL NEWS

University of Cambridge

On Saturday last the regent house approved the recommendations made by the faculty board of medicine concerning the abolition of the thesis for the M B degree (see The Lancet, Feb 6th, p 335)

On Feb 20th the following degrees were conferred —

M B B Chir—W L Petter E B McDowall, J F Goodall, G S Steele Perkins and Christopher Hardwick

M B—E E Pochin and W F Richards

B Chir—G O Brooks

Major Thomas Dalling, M R C V S, of the Wellcome Physiological Research Laboratories, has been elected to the chair of animal pathology in the university

University of London

At a meeting of the senate on Feb 17th the title of professor of biochemistry in the University was conferred on Mr A C Chibnall, Sc D, in respect of the post held by him at the Imperial College (Royal College of Science) Prof Raymond Pearl, who holds the chair of biology at the school of hygiene Johns Hopkins University, Baltimore, was appointed Heath Clark lecturer for 1937

University of Glasgow

Dr J B Rennie assistant physician to the Royal Hospital for Sick Children, Glasgow has been appointed university lecturer in medicine

University of Birmingham

Dr Henry Pratt Newsholme, medical officer of health for Birmingham since 1927, has been appointed to the university chair of hygiene and public health in succession to the late Sir John Robertson

Dr Newsholme who is a nephew of Sir Arthur Newsholme obtained first class honours both in the London B Sc and the Oxford science schools He graduated in medicine from St Thomas s Hospital in 1910 became M D Oxon in 1915 and F R.C P Lond in 1927 Before going to Birmingham he was medical officer of health for the North Riding of Yorkshire and the county borough of Croydon

Society of Apothecaries of London

At recent examinations the following candidates were successful —

Surgery—E S Dismorr Univ of Camb and St George's Hosp, B T Jones St Mary's and West London Hosps, J E R Palmer, St. Mary's Hosp B A R Pitt Guy s Hosp A W B Perren Univ of Sheff J R Rocyn Jones Welsh National School of Medicine and R L Williams, London Hosp

Medicine—J D Anderson, St Bart. s Hosp R F B Bennett, Univ of Oxf and St George s Hosp H A Bhuttacharji Univ Coll Hosp S M M Niall Royal Colleges Edin G G Sahasrabuddhe, Bombay and West London Hosps, R G Stitt Westminster Hosp and G Theophilus Univ of Oxf and St. George s Hosp

Forensic Medicine.—J D Anderson St Bart s Hosp R F B Bennett Univ of Oxf and St George s Hosp H A Bhuttacharji Univ Coll Hosp, J T Boocock, Univ of Leeds S M M Niall Royal Colleges Edin G G Sahasrabuddhe Bombay and West London Hosps R G Stitt Westminster Hosp and G Theophilus Univ of Oxf and St George s Hosp

Midwifery—J D Buckner, Guy s Hosp, J W Cazalet Bombay and West London Hosps F T Futers King's Coll Hosp O I Green Univ of Oxf and Guy s Hosp W A Groom Guy s Hosp S J Nathan Charing Cross Hosp and R G Stitt Westminster Hosp

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine surgery, and midwifery R F B Bennett, H A Bhuttacharji, J T Boocock, J W Cazalet, E S Dismorr, F T Futers, J E R Palmer, J R Rocyn-Jones, and R L Williams

The guests at Tuesday's livery dinner of the Society of Apothecaries included the Lord Mayor and Sheriffs and Mr Montagu Norman, governor of the Bank of England In welcoming them Dr A P Gibbons, the master spoke of the ways in which the city looked after its children from the cradle to the crematorium and recalled the impression made by the Lord Mayor's procession—'we call it procession' in the City"—on his small son who came home and said his grace as "For what we are about to receive may the Lord Mayor make us truly thankful. In reply, the Lord Mayor quoted the rejoinder of a Londoner to an American "The Ohio is just water; the Mississippi is just mud but the Thames is liquid history The toast of the Guests proposed by Dr R. H. Hayes as junior warden drew responses from Sir Cuthbert Wallace P.R.C.S and Dr G N B Sebastian master of the Skinners Company Sir Cuthbert congratulated the apothecaries on having like the surgeons thrown off that domineering person the physician He expressed anxiety about the future of surgery in face of the new generation of scientific apothecaries and scientific physicians steeped in preventive medicine and immunology The surgeon might still be able to look after accidents but the Minister of Transport was trying to make the roads so safe that motorists could collide no more than electrons can It was sinister that the president of the surgeons should be associated with the master of the skinners; but at least the surgeons put most of it back. Dr Sebastian produced (not very convincing) arguments to show why 80 per cent of the inhabitants of prisons are drawn from the ranks of after-dinner speakers

Hunterian Society

The annual dinner of this society celebrating the 209th anniversary of the birth of John Hunter was held at the May Fair Hotel on Feb 17th with Mr H L. Attwater the president in the chair After the loyal toasts that to the immortal memory of John Hunter was drunk in silence Mr Albert C R Carter in proposing the health of the society said that he himself belonged to another society—the Knights of the Round Table—that had similar ideals of honour and chivalry ideals that had a world wide influence in the present days, and Hunter could be likened to King Arthur for his courage and devotion to duty The president responding said that the society had been through difficult days and had narrowly escaped amalgamation with another but it was growing monthly in numbers It owed its salvation largely to Mr Mortimer Woolf now editor of the transactions. On behalf of the council and fellows he presented Mr Woolf with a silver ink stand which he received with evident surprise and gratification. Mr Attwater announced that the gold medal given by the society for competition throughout the Empire had been awarded to Dr L. J A Parr of Sydney Australia Dr George Armour of Woodhall Spa was second The toast The Lord Mayor and the Corporation was proposed by Dr W H F Oxley who voiced the society's thanks for the Lord Mayor's generosity in lending a room in the Mansion House for some of the meetings; he was sure the place helped to enhance the society's prestige The Lord Mayor Sir George Broadbridge responding said how valuable he and the civic authorities found the work of the medical profession Mr Mortimer Woolf wittily proposed The Guests and Kindred Societies, welcoming especially the ladies. All doctors he said are the better for their wives and this was particularly true of John Hunter whose consort was a highly cultured woman a composer of songs and a poet Serjeant Sullivan said that the only toast a doctor could genuinely propose was Prosperity Long Life and Bad Health. He added however that the medical profession was largely responsible for the revolution in the state of the nation since his youth. He contrasted with its present condition the misery and degradation in the East End of London of those days where he never saw a child smile Sir James Hartigan said that the Army Medical Services remembered with gratitude how a threat of consumption drove John Hunter to take a staff surgeoncy and join the troops in Portugal Although he was later responsible for equipping medically no less than ten overseas expeditions, by his superhuman energy he still kept his position as the unquestioned head of his profession War to-day was very different however from what it was in Hunter's day Sir James quoted Lord Moynihan's remark that he had seen in one hour more destruction of life and limb than a surgeon could hope to save in a life-time The coöperation of every branch of medicine was essential but if in spite of statesmen's efforts, the emergency arose he was sure this coöperation would come Sir William Willcox, concluding the replies for the guests, paid a tribute to the society not only for living up to the high standards of Hunter but for its sociableness and he wished it prosperity and success on behalf of kindred societies During the evening Mr Tom Clare and Mr Robert Easton entertained the company with songs

Society of Radiographers

The annual dinner of this society was held on Feb 20th with Miss K. C Clark in the chair It marked the attainment of a membership of more than one thousand and the completion of ten years in the office of hon. secretary by Mr Frederick Melville During the evening Dr Duncan White was presented with the Stanley Melville medal Among those present were Mr G W C Kaye, D.Sc who proposed the health of the president and Prof J A. Crowther president of the Institute of Radiology Dr R M Beath chairman of the Ulster Radiographic Society; Dr Struthers Fulton chairman of the Scottish branch of the society; Dr Angus Macrae Dr Charles Read chairman of the Scottish Radiographic Society and Dr L A. Rowden.

British Health Resorts Association

A conference of this association will be held at Bournemouth on Saturday March 13th. In the morning Lord Horder will open a discussion on Wintering in England and in the afternoon Prof Kestner of the Rowett Institute Aberdeen will speak on the curative action of sea climate Further information may be had from the secretary of the association 109 Piccadilly W 1

Lebanon Hospital for Mental Diseases

The thirty-eighth annual meeting of this hospital will take place at the Cora Hotel, Upper Woburn place London W C on Tuesday March 2nd at 3 P.M when Dr R Percy Smith, the president will take the chair The speakers will include Dr Nathan Raw (Lord Chancellor's visitor in lunacy) and Dr Tylor Fox (acting chairman of the hospital)

Medical Tour in the Mediterranean

A medical tour organised by the Société Médicale du Littoral Méditerranéen, will take place from March 21st to 28th All the resorts on the French Riviera from Hyères to Mentone will be visited and receptions and scientific demonstrations will be held A children's welfare congress, concerning climatic conditions will also take place during this period Particulars can be had from the Society 24 rue Verdi Nice (A M) and the French Railway and Tourist Office 170 Piccadilly London W 1

Research Fellowship for Tavistock Clinic

The trustees of the Rockefeller Foundation have given a further research fellowship for a year to the Institute of Medical Psychology (Tavistock Clinic) The fellowship is held by Dr A T Macbeth Wilson who is engaged on the study of certain diseases—peptic ulcer essential hypertension diabetes mellitus and Graves's disease—whose onset has often been related to emotional disturbances in the lives of patients

Irish Medical Research Council

The first meeting of the recently incorporated Medical Research Council of Saorstat Eireann was held on Feb 10th The following members were present: Prof R P Farnan (chairman) Prof J W Bigger Prof J F Donegan Prof W J E Jessop Dr J McGrath Prof H Moore Prof T G Moorhead and Prof J M O Connor The following officers were appointed hon treasurers Dr McGrath and Prof O Connor hon secretary Prof Bigger; and solicitor Mr P H O Reilly

Nicol Rankin Memorial Fund

A fund has been opened to provide a permanent memorial to Mr Nicol Rankin at the Central London Throat Nose and Ear Hospital with which he was closely associated as a surgeon and a member of the committee of management Mr Rankin died in 1931 It is proposed to name a cot in the children's ward of the hospital after him Gifts for the fund should be sent to the treasurer Lord Erskine of Restormel Central London Throat Nose and Ear Hospital, Gray's Inn road W C.1

MARTIN—On Feb 14th at Madeley road Ealing W James Hamilton Martin Inspector-General of Hospitals and Fleets R.N (Ret), D.S O M R.C.S Eng aged 95

MOLLOY—On Feb 19th, at a nursing home Major Leonard Greenham Star Molloy, D S O Knight of Grace of the Order of St. John of Jerusalem M D Dub of Sterling street S W

RANSOM—On Feb 22nd at Weston-super Mare Frederick Parlett Fisher Ransom M D Edin late Professor of Pharmacology University of London aged 87

REY—On Feb 13th at Bognor Sussex Jules Frederick Rey M R.C S Eng

STALKARTT.—On Feb 18th at Alverstoke, Hants, Major Charles Edward Grey Stalkartt M.D Edin. R.A.M.C retired in his 7 nd year

N.B—A fee of 7s. 6d. is charged for the insertion of Notices of Births Marriages and Deaths

LANGLEY MEMORIAL PRIZE —This prize of the value of £21 is open to officers of the Colonial Medical Service who are serving or who have served in West Africa. It will be awarded for the best paper submitted on a topic falling within one of the following subjects: tropical medicine or surgery; tropical hygiene and sanitation; or tropical entomology and parasitology Special consideration will be given to original work Papers, which may consist of either published or unpublished work must be delivered to the secretary London School of Hygiene and Tropical Medicine Keppel-street Gower-street London W C 1 by Oct 1st

NOTES, COMMENTS, AND ABSTRACTS

MANIPULATIVE SURGERY

SIR HERBERT BARKER'S DEMONSTRATION AT ST THOMAS'S

Case Reports and Notes by

W Rowley Bristow, F R C S

On July 22nd, 1936, at the invitation of the British Orthopædic Association, Sir Herbert Barker gave a demonstration of his methods of manipulation at St Thomas's Hospital.[1] He treated 18 patients on that afternoon He visited St Thomas's the day before the demonstration, and saw a number of patients who had been collected, that he might choose those on whom he wished to demonstrate He made his selection from these, and also brought to the demonstration a number of patients who had consulted him and were willing to be manipulated at the hospital

It was clearly pointed out at the meeting that Sir Herbert Barker had very kindly accepted the invitation to demonstrate his methods of manipulation, that the meeting was in no sense a tribunal to judge the value of manipulation in surgery, or even necessarily to estimate its value to these particular patients The members were grateful to Barker for showing for the first time to a body of surgeons the actual technique which he employed Barker was invited to give this demonstration because the Association felt that his record and the position which he had attained more than compensated any possible objections which this break with tradition might be thought to raise

Barker, trained as a bone setter, coined the name "manipulative surgery" as being more correctly descriptive of his work, and for many years, and indeed all his life, fought hard both to improve its status and to obtain recognition for what he rightly called "a hinterland of surgery"

Since the meeting many inquiries have been received from members to know what happened to the patients, and Barker himself is anxious that some report should be published as to the success or failure of what he did on the occasion of his demonstration and at his subsequent visits to the hospital. Barker visited St Thomas's again on July 27th and Sept 10th and saw the patients, and in some instances manipulated a second and even a third time with or without gas anæsthesia

A detailed report of what happened to each individual patient forms a part of this communication, and indeed is all the report that is needed, but it is thought that some general observations and a critical survey may be of interest.

Case Reports

Case 1 —*Recurrent dislocation of shoulder* in a man Shoulder troublesome for 15 years Has "dislocated" hundreds of times sometimes daily Before Barker saw this patient he wrote 'I have consulted several doctors who told me that there is no cure, and that the state of my shoulder must be regarded as permanent" Has never had to be reduced by a doctor

July 22nd, 1936 Manipulated under nitrous oxide

Patient reports (July 27th) "Cranked a car next day" Nov 18th 'Perfect"

Barker reports "It is over four months since I treated this case, and only during one period of a week did the shoulder give any trouble at all and this was towards the end of September No sign of weakness since then The muscular contour of the shoulder is now normal, and the patient can stand any kind of strain I believe he is quite cured"

February, 1937 Patient remains well

Case 2 —*Recurrent dislocation of shoulder* in a man of 25 Went out at rugger, reduced on the field Two months later, out again at rugger, reduced by doctor Has been out eight times

Sept 10th, 1936 Manipulated under nitrous oxide

Results —Patient writes "No trouble Not doing heavy work Arm feels stronger and has more confidence"

February, 1937 Patient remains well

Comment —Barker is very insistent that in his experience manipulation performed as he performs it permanently cures these patients with recurrent dislocation of shoulder

Case 3 —*Stiff, painful shoulder* in a woman of 61 Six weeks' history, insidious onset, getting worse Abduction full rotations limited

July 22nd, 1936 Manipulated

July 23rd Remanipulated under nitrous oxide

Sept 10th Remanipulated under nitrous oxide

Result —Little or no improvement

Comment —This case was not of Barker's choice and he was not sanguine about the results of manipulation, but he thinks further manipulation will result in a cure

Case 4 —*Tennis-elbow* in a medical man Onset April, 1936

July 22nd, 1936 Manipulated

July 23rd Remanipulated under nitrous oxide and later again manipulated

Patient reports "After first manipulation I was much better, after the second rather worse, and much better after the third The elbow has gradually got well, and since October I have felt nothing of it I can now swing an axe in comfort"

Barker reports "This patient would have been right in a week had I been able to see him on consecutive days"

Case 5 —*Tennis-elbow* in a man Onset May, 1936

July 22nd, 1936 Manipulation under nitrous oxide

Patient says "Gradually got better Able to play tennis and won a tennis tournament soon after manipulation Backhand still a trouble" (Sept 10th)

Later report "Cured"

Case 6 —*Tennis-elbow* in a man Onset nine months ago

July 22nd, 1936 Manipulation under nitrous oxide

Sept 10th Remanipulation

Barker's comment 'When I see them again, I always put them through the same manipulative range, to be sure they are free Hence the note, remanipulation Sept 10th"

Patient says "Able to play tennis normally in ten days after first manipulation Thank you for getting rid of a trouble which had strenuously refused to move under other treatment"

Comment —Rapid cure

Case 7 —*Osteo-arthritis of knee* in a woman of 57 Six months' pain Extreme of movement limited

July 22nd 1936 Manipulated under nitrous oxide

July 23rd and 27th Remanipulated

Result —Greater range of movement but more pain.

February, 1937 Definitely improved

Comment —This patient was not one of Barker's choice, but he desires to continue treatment He thinks perfect result probable

---

[1] A brief account of this demonstration was published in The Lancet 1936, 2 252 The late results are now recorded by Mr Bristow —Ed L

CASE 8 —*Derangement of internal semilunar cartilage* in a woman of 20
July 22nd, 1936 : Manipulation under nitrous oxide
July 27th : Remanipulated
Result —Failed to respond to two manipulations at a very short interval. Knee gave way on two subsequent occasions. Has since had a torn semilunar cartilage removed at operation
Barker says he would like to have manipulated this case several times more under gas, and that he considers one manipulation under an anæsthetic was insufficient before finally deciding to operate though he thinks the case was probably one for the open operation

CASE 9 —*Internal derangement of knee internal semilunar cartilage* in a man of 30 Injured 13 years ago then got well in six months No trouble for next ten years Has given way two or three times since Knee normal on examination
July 22nd 1936 : Manipulated under nitrous oxide
Barker reports Since the manipulation, has only had slight mishap on one occasion towards end of second week in November causing some effusion. Perfect comfort for four months. Consider cure is likely ultimately ; meantime joint is greatly improved

CASE 10 —*Torn internal semilunar cartilage* in a man of 27 Knee locked and unlocked under gas in June 1936 Knee normal on examination.
July 22nd 1936 : Manipulation under nitrous oxide
July 23rd and Sept 10th Remanipulated
Nov 19th : Remanipulated under nitrous oxide
Result —Failed to respond to treatment. Knee keeps giving way and has been out for two days at a time
Barker thinks this is definitely a cartilage injury calling for open operation.

CASE 11 —*Internal derangement of knee* in a man of 26 Two years ago kicked on outer side of the knee Complains of constant pain on the outer side Has never locked clicked or let him down Knee normal on examination
July 22nd, 1936 : Manipulation under nitrous oxide
Patient writes After manipulation knee felt normal."

CASE 12.—*Adhesions in hip and knee* in a man of 30 Said to have dislocated hip in November 1935 Hip held flexed and adducted Limited range Knee also stiff
July 22nd 1936 : Manipulation under nitrous oxide
July 23rd and 27th Remanipulation
Result —Hip much freer Knee normal. Walks with a limp Complains of pains in the head.

Comment —Definitely improved by manipulation Probably will be cured when compensation is settled

CASE 13.—*Plano valgoid feet* in a child of 11 Twelve months aching both feet after exercise Both feet mobile
July 22nd 1936 : Manipulation under nitrous oxide
Three subsequent manipulations
Mother writes We are delighted to find that she is really able to enjoy life as children of her age should running about and playing games The feet are giving no trouble Previous to your manipulation a local orthopædic surgeon could offer no cure and advised no form of exercise to tire the feet.

Comment —Cured

CASE 14.—*Pes planus and hallux rigidus* in a child of 13
July 22nd 1936 : Manipulation under nitrous oxide
Sept 10th Remanipulated
Mother writes Playing lacrosse learning dancing No pain. Manipulative surgery seems wonderful to us.

Comment —Cured Given proper shoes and exercises after manipulation.

CASE 15 —*Stiff arthritic foot hallux rigidus* in a woman of 50. Fifteen years history
July 22nd 1936 : Manipulation under nitrous oxide
Patient says "Cured No pain
Barker writes Hallux rigidus of 15 years standing Great relief at once Four subsequent manipulations rendered the toe quite comfortable and restored normal movement. I believe such a condition is considered incurable in a patient of her age

Comment.—Improved This patient had been under an orthopædic surgeon and had tried every kind of non-operative treatment Her symptoms undoubtedly relieved by repeated forcible manipulation—a treatment not usually applied for this condition

CASE 16 —*Lumbosacral and sacro iliac strain* in a woman of 46 Over two years low back pain No sciatica
July 22nd 1936 : Manipulation under nitrous oxide
July 23rd and Sept 10th : Remanipulated.
Patient writes "Cured Life's a joy !
Barker writes Daily improvement resulting in perfect cure in a few weeks. Had been under hospital and private treatment for two years without benefit

Comment —Complete cure in a most difficult patient

CASE 17 —*Lumbosacral strain* in a woman of 37 Pain in the low back. Eleven years standing since the birth of a child No sciatica Extension of the lumbar region limited
July 22nd 1936 : Manipulation without nitrous oxide
Patient says She noticed no difference for 14 days Since then has gradually got better Not perfect yet

Comment —Is still improving Will probably be cured.

Critical Survey

CHOICE OF PATIENT

He chose the patients well and refused any that he thought unsuitable for manipulative treatment One or two—e g one woman with an arthritis of wrist—he refused but agreed to try at our request. He liked to treat a patient with symptoms and without physical signs—e g to manipulate a mobile foot—as well as those with definite limitation of movement or even actual deformity It is only fair to add that he tackled some unattractive problems

TECHNIQUE

He uses gas (nitrous oxide) anæsthesia but sometimes simply sprays the part with ethyl chloride and at subsequent manipulation does not hesitate to use gas again several times if necessary The patient is in a low easy arm chair for manipulation of the knee or foot—a good position which enables the operator to apply force conveniently the patient's body acting as a good counter A very low couch or plinth is used for manipulations of the back sacro iliacs or hip joints For the shoulder he prefers a special chair a stool with a straight back which does not impede the movements of the arms The position of the patient and the operator is well arranged.

Barker has powerful hands and uses his body weight to apply the accessory force and leverage In all grips and manipulations he employs strong traction and considerable force is not content to put a joint through its anatomical range but treats each as if it were a ball and-socket.

In manipulating the *elbow* for the strain of the common extensor group the so-called tennis-elbow he not only flexes and extends, with traction and in all degrees of pronation but in addition forcibly abducts and adducts the joint—that is forces lateral hinge movement His technique in such cases is the most thorough and forceful we have seen. He maintains that uncomplicated cases of tennis-elbow should be cured in a few days and often with only one or two manipulations if given during consecutive days.

In manipulating the *foot*, he forces full range, particularly towards adduction and plantar flexion at the mid tarsal joint. He does not, as has been rather forcibly stated, attempt anything in the way of flattening or breaking down the arch of the foot. In cases of rigid flat foot with deformity, he forcibly reshapes the foot, never uses special shoes, supports, or plaster of-Paris, and repeats his manipulations as often as necessary under nitrous oxide anæsthesia. The patient is encouraged to walk immediately after manipulation.

His belief in traction—and it is good—is well shown in his handling of the adult hallux rigidus. An elderly female, with this deformity, was undoubtedly helped, and her symptoms disappeared, after his manipulation of this joint; with forcible traction as the constant factor, the great toe was forced through all its range, plantar flexion, dorsiflexion, abduction, adduction, and circumduction. This deformity is one which we are not accustomed to treat by manipulation, but with this patient it undoubtedly succeeded.

AFTER TREATMENT

Barker sees the patient on the day following the manipulation, and again two or three times, or as many times as he thinks necessary. He instructs them what exercises to perform. He has evolved his own exercises, and they are good. He relies on no other help or assistance, and does not employ a masseuse or gymnast as we do. I think he would save time and fatigue if he were assisted as we are by first rate trained gymnasts rather than undertake all this after treatment and supervision himself.

I saw him handle one woman whose knee he had manipulated twice previously for a chronic rheumatism, really a mild subacute arthritis of knee. She hobbled into the room. After a third manipulation Barker spent a quarter of an hour walking her round, teaching her to walk, insisting on an equal length of stride, and so forth, and she walked normally. He is very thorough, and conscientious, and careful in detailing and in supervising the after-treatment of the patients he manipulates.

Barker possesses a very strong personality. Once he undertakes the treatment of a patient, he does not visualise the possibility of failure. This tremendous optimism must have and does have its effect upon the patient. He claims for the actual manipulation all the credit, but some part, and in many instances a large part of the cure is effected by the man himself. This is no prerogative of Barker or any other expert in treatment. It is possessed by all who are successful. It is a characteristic, which Barker shares with others, but he is quite unconscious of it, and has argued with me that it is all manipulation and that his personality plays no part, or at best a very minor one.

Whilst before the war manipulative surgery was to the great bulk of the profession a very "hinterland of surgery," as Barker then repeatedly told us, perhaps he does not fully recognise that the post-war epoch and the rise of orthopædic surgery have removed this reproach to medicine. Having spent so much of his life fighting for a cause in which he firmly and justly believed, he fights for it still and does not quite realise that his battle is won. Orthopædic surgeons now practise manipulation as an essential part of their specialty.

Conclusion

From Barker's demonstration, certain excellent details in his technique will probably be followed. He taught the value of repeated manipulation, the value of traction, the personal supervision and attention to exercising the joint in all directions afterwards, and above all, I think, the splendid optimism which is essentially a part of treatment, and a necessary part, in helping those with long standing disabilities, whose confidence has been rudely shaken by failures of the earlier efforts at cure.

It is due to Barker to say that but for his pioneer work the manipulative field of orthopædic surgery would not occupy the position it does to day, and that had his offers to demonstrate his technique been accepted twenty five years ago the general utilisation of this branch of therapeutics would not have been so long delayed.

PUBLIC VACCINATION

THE activities of the Association of Public Vaccinators of England and Wales during the last 17 years were reviewed at the annual meeting of the association, held in London on Jan 30th, by Dr James Bennett in a presidential address. In addition to giving members assistance in the solution of difficulties which from time to time arise as between the public vaccinator and his employing authority, and attempting to promote the interests of public vaccinators as a whole, the association have made an appeal to medical officers of health to have in mind the safeguarding of the general cause of vaccination, and have endeavoured in other ways to combat the idea that compulsory vaccination should be done away with. The association believe and have tried to convince the Society of Medical Officers of Health, that if compulsory vaccination, and with it the organised staff of vaccination officers were abolished, "vaccination would evaporate." They hold that the experience gained from voluntary diphtheria immunisation, where after intensive propaganda only 10 or at most 20 per cent of children have been immunised, and this only in a very few places, justifies their view that such element of compulsion as still remains is absolutely necessary if small-pox is to be prevented.

THE TRANSPARENT WOMAN

THIS name is given to a life-size figure of a woman, constructed of a transparent, non-inflammable material known as "cellhorn." It stands on a large base, which contains a system for lighting both the whole figure and each organ in the body singly by means of twenty pairs of low-temperature lamps. These can be lit up in sequence, or separately, and the name of each part appears on the base while it is being demonstrated. The organs are shown in their natural sizes and colours, and were made with the coöperation of anatomists, artists, and sculptors in the Hygiene Museum of Dresden, from photographs of normal specimens. Even such detailed structures as the ossicles of the ear and the sesamoids of the thumb are exactly reproduced. The model belongs to S H Camp and Co, Ltd, makers of anatomical supports, of Jackson, Mich, U S A, and 252, Regent-street, London, and is intended for the education of the lay public in matters of general health. It is now on a transcontinental tour of the American cities, accompanied by a medical lecturer. The same firm also produces a book of "Anatomical studies for physicians and surgeons," with 32 well-drawn plates, mainly of the abdomen and of the structures maintaining posture.

HOVE HOSPITAL.—On Feb 3rd Princess Helena Victoria opened extensions at this hospital, which have cost £35,000. They include an out-patient department, nurses' quarters, an operating theatre, an X ray and massage department, while the number of beds has been increased from 23 to 50.

THROMBO ANGIITIS OBLITERANS *

BY E D TELFORD B Chir Camb F R C S Eng
EMERITUS PROFESSOR OF SURGERY UNIVERSITY OF MANCHESTER

(From the Department of Clinical Research in Disorders of the Autonomic Nervous System Manchester Royal Infirmary)

WE owe the term thrombo angiitis obliterans to Buerger who published his very complete and documented account of the condition in 1924. The disease had of course been recognised long before and sporadic cases had been described by v Winiwarter Parkes Weber and others A variety of names—endarteritis obliterans, juvenile and presenile gangrene—had added to the confusion. Buerger s title which has come into general use is based on his observation that the condition is by no means restricted to arteries and that phlebitis plays an important part in a proportion of cases (in my experience about 25 per cent) and may be antecedent or intercurrent in the development of the disease

Thrombo angiitis obliterans begins mainly in the medium-sized blood vessels of the limb such as the anterior and posterior tibials From these points it spreads, usually slowly but sometimes by acute exacerbations both upwards and downwards it may also develop in patches separated by intervening stretches of normal artery In certain cases in younger men it appears to begin in the digital arteries of the foot It is rare in the arms and I have never seen it there until it has made grave progress in the legs. It has been described in other arteries—e g the spermatic one of my patients died from involvement of the inferior mesenteric artery and in another who died at the age of 20 from angina the changes found in the coronary arteries were histologically identical with those of thrombo angiitis obliterans.

The disease is not only liable to exacerbations but is very variable in its course in different patients Attempts have been made to classify it into groups based on the rate of progress but in a large series it is doubtful if such grouping can be usefully or even justifiably done One of my patients had the disease for 38 years and suffered no more than a trivial loss of portions of two toes during this long time. Another died because the thrombosis ascended to his inferior mesenteric artery within seven months of the onset of claudication and between these cases there are innumerable variations Needless to say it is this variability which renders so difficult the judgment of therapeutic values

Although as yet of unknown origin the disease has the histological features of an inflammatory lesion—thrombosis occurs and is followed by organisation of the clot This although often alleviated to some extent by canalisation of the fibrous tissue causes the grave embarrassment of the circulation to which the symptoms are due

As regards sex incidence every writer has been struck by its rarity in women Among several hundred cases I have seen but three in women and Buerger s figures show no more than three in five hundred This very striking incidence must of course have a bearing on causation but so far its true significance has not been found neither is it clear why the disease should be found so often in the lower extremities. Differences of tone no doubt exist between the arteries of the legs and arms but no sufficient explanation of the predilection of the disease for the legs is forthcoming It is of interest to note however that in epidemics of ergotism in Eastern Europe the lesions are found more often in men and more usually in the legs

Stress was laid by earlier writers on the predominantly Jewish racial origin of the patient but wider experience has shown the fallacy of these statements In my own series there is no greater proportion of Jews than one would expect from the general population of Manchester Moreover large series of cases have been recorded as occurring in the natives of China and Siam. It is not very easy to determine the age of onset of the disease because we do not usually see cases until claudication has become severe and it is certain that the lesion has been present for a long time possibly some years. The majority of cases are found in the decade 30–40 years but a considerable number occur before this age In one remarkable case in which the diagnosis of thrombo angiitis obliterans appeared the only possible one the symptoms began at the age of 8 years when it was noticed that the boy could not play with his fellows owing to crippling pains in the calf on exertion The condition slowly worsened and at 10 he had lost the half of the right foot and all toes of the left foot from gangrene

Pathology

The microscopical changes have often been described and there is general agreement as to the findings It is worth while to point out that for the purpose of histological examination the material should not be chosen from a limb which is the site of infection The changes induced by a superadded infection are more widespread than is generally recognised and may obscure the picture

The process is essentially one of gradually increasing fibrosis. This is at once apparent when the attempt is made to dissect out material for examination It is not uncommon to find that the neurovascular packet in the popliteal space is embedded in a mass of fibrous tissue so dense that separation into artery vein and nerve is no longer possible. The artery is itself converted into a firm solid rod. This fibrosis of the artery may be patchy and limited to a definite stretch of the vessel—e g the popliteal artery may be occluded but the superficial femoral may be patent or the posterior tibial may be destroyed whilst the anterior tibial shows little or no change The fact that the disease may be extreme in one section shading off to the normal above and below gives one the opportunity to study the changes in various degrees of their development At the outset there is a lymphocytic invasion of the coats of the arteries and veins The cells are replaced by fibrous tissue and new vessels are seen extending into the media from the adventitia. Whilst these changes are proceeding clot is deposited upon the intima and the process of organisation of this clot begin Whilst organisation is taking place collections of lymphocytes arranged in a fashion suggestive of tubercles may be seen. These together with the rest of the tissue are gradually replaced by fibrous tissue This fibrous tissue is recanalised to some extent the small channels showing an endothelial lining and in some cases a thin coat of smooth muscle Ultimately the newly formed fibrous tissue in the media and adventitia appears to become denser and to contract This may be a contributory factor in the onset of gangrene by its pressure upon the connective tissue and channels in the lumen. The histological examination shows that the condition is more widespread than the clinical picture would suggest, both superficial and deep veins and arteries being affected, but all the vessels in one region are not equally affected.

---

* A lecture delivered for the University of London at St Mary s Hospital medical school on Feb 23rd 1937

The veins show similar changes whilst the nerves show the changes of a secondary involvement in fibrous tissue.

POSSIBLE CAUSES

Whilst there is general agreement on the histopathology, it is very different when one comes to consider the cause of these grave structural changes. It may be said at once that the cause is at present unknown and all that one can offer is a catalogue of the various suggestions which have been made by different observers.

It is plain that *syphilis* has nothing to do with the disease. Among over 200 of our cases the Wassermann reaction was positive in but 3.

Tobacco in the form of excessive cigarette smoking has been incriminated by many writers. Paper and tobacco have alike been blamed. There is a certain amount of experimental evidence in favour of this view. It has been shown that when tobacco is smoked there is a drop in the cutaneous temperature of the digits, and that this is due to a toxic agent is shown by the fact that the drop does not occur if the smoke be filtered. Further, the number of patients who admit to smoking cigarettes in excess of say 15 a day appears considerable in a series of cases. One can only say that tobacco may be a contributory factor but is certainly not the direct and only cause. A number of cases have been seen in both men and women who have never smoked. In one of my cases the disease occurred in a most severe form, ending in a double amputation within three years of its first symptom, in an athlete who for reasons of training had never smoked.

Our Manchester cases include a large number of men of first-rate physique who have been keen athletes in their youth, and there appears also to be an unusual proportion of men who have followed occupations—e.g., navvies, slaters, and other outdoor workers—in *wet and cold*. But these can be no more than possible contributory causes. Routine examination of the blood for sugar, urea, calcium, phosphorus, and for coagulability time has yielded no clue.

A point worthy of inquiry and one which we are following up is the possible existence of a similar condition in horses.

SPASM OR INFECTION?

In the present absence of exact knowledge of the cause it may be more profitable to discuss the question on broader lines and to begin with the problem of whether it is due to spasm or infection.

This question is far from academic; it is very real, since on the answer will depend the curability of the disease by section of the sympathetic supply to the vessels. If the disease is truly spastic, the operation of sympathectomy will not merely alleviate but should cut short further progress. If on the other hand the condition is toxic or infective, division of the sympathetic supply will not arrest the disease though it might be of real value in bettering the condition of the limb by dilating such collateral paths as are still healthy.

In favour of the spastic theory the statement is made that on exertion the limb is blanched. This phenomenon is due, I believe, to the muscular action causing removal of blood to take place more quickly than blood can be replaced by the embarrassed arteries. Elevation of the limb will produce the like result without any question of spasm. It is possible also to adduce arguments from cases of the Raynaud phenomenon, cervical rib, and ergotism which tend to show that arterial spasm if sufficiently severe and prolonged will cause thrombosis.

The arguments in favour of a toxic origin are much more weighty. The associated phlebitis which in some patients appears to precede the onset of arterial disease suggests a toxic origin. In this respect the relation of thrombo-angiitis obliterans to the migrating forms of phlebitis needs fuller investigation.

Rabinowitz (1923) claims to have isolated a Gram-negative rod-shaped organism and to have produced by injection of the bacillus the same lesion in the ears and feet of rabbits as occurs in the human leg. These findings, however, have not to my knowledge been confirmed by other observers.

Perhaps the most important evidence on the question of a spastic or toxic origin of thrombo-angiitis obliterans is that obtained by careful follow-up during a number of years of those patients who have been treated by sympathectomy. These I will deal with under the head of results, but it is now evident that excellent as are the results of sympathectomy in many cases there are some in which one can only conclude that the disease has progressed. It is from these that I am driven regretfully to the conclusion that the disease is toxic rather than spastic.

It is also worthy of note that an examination of many hundreds of sections taken from the material removed at ganglionectomy operations on these cases, controlled by many sections taken from normals at various ages, shows nothing abnormal and certainly yields no evidence of any pathological alteration in the sympathetic chains. The observations, however, concern merely the pathway; there may none the less be some lesion of the higher centres.

Symptoms

Although a few of the more intelligent and observant patients may give a history of coldness of the feet and may have noticed blanching after walking, the average patient comes under observation on account of claudication. His walking distance may be of the order of a quarter of a mile, when walking at his usual pace on the level. It will be shorter if he walks quickly or uphill. His pain is usually in the calf but may be in the sole of the foot. This latter symptom is more common in the younger men and indicates that the disease is more severe in the small arteries of the foot. These younger patients exhibit blanching alternating with cyanosis which may lead to a diagnosis of Raynaud's disease. If these cases are followed up they are found to develop into true and severe thrombo-angiitis obliterans although in their earlier stages they have presented what is best regarded as one type of Raynaud phenomenon. In these cases a good pulse may be felt in the posterior tibial or even in the dorsalis pedis arteries. Usually, however, when a patient comes for examination no pulse can be felt in the posterior tibial or dorsalis pedis, and seldom in the popliteal, but almost always there is a good pulse in the common femoral artery. It is only in severe and late examples of the disease that the common femoral artery is thrombosed.

As the disease progresses the walking distance is further reduced and rubor begins to make its appearance. This rubor is most evident in the dependent position and disappears on elevation of the limb above the heart and in walking In the course of time the patient begins to suffer when at rest in bed from aching or actual pain, usually in the feet This he discovers is eased by the dependent position and by cold, and he usually learns to hang his leg out of the bed to alleviate it.

Eventually some form of trophic trouble is likely to arise. The most common type is an infection by the side of the nail of the great toe A very persistent onychia results and in many patients the nail has already been removed with the result that a chronic, very indolent ulcer is left over the nail bed. This shows no tendency to heal and makes no attempt to develop a new nail. The condition of the foot is now very precarious and any slight accident or further infection may precipitate the terminal gangrene By no means does every case end in gangrene it is however a common ending and by some writers has been put as high as 50 per cent.

The condition of rest-pain with its worry and loss of sleep produces much deterioration in general health and in the later stages there are found some of the most worn and emaciated patients that it is one's misfortune ever to see

Two points strike one in the examination of a large series of cases Firstly true thrombo angiitis obliterans is always bilateral but the patient will usually stoutly aver that only the one leg gives him trouble This is because the worse leg invariably pulls him up before the other leg has reached the stage of claudication. Clinical examination and above all the claudicometer (Simmons 1936) will show that the supposedly good leg is but little better than the one blamed by the patient Secondly great reserve should be used in giving a prognosis of the less involved limb It is quite common to find that this limb deteriorates more rapidly than its fellow and is likely to prove eventually to be the worse of the two

Diagnosis

It is of course only in recent years that the diagnosis of thrombo angiitis obliterans has been made with confidence It is therefore not surprising to find that many of these cases have had prolonged treatment for rheumatism, fibrositis, and very commonly for flat-foot. It should be realised that when a patient of middle age begins to complain of pain in the lower limb after exertion careful investigation should be made into the condition of the peripheral circulation

There are however three vascular lesions which may be mistaken for thrombo angiitis obliterans They are arterio sclerosis, the Raynaud phenomenon and the embolic exacerbations of arterio sclerosis. Confusion is most frequent between thrombo angiitis obliterans and arterio-sclerosis especially as the symptom of claudication occurs in both diseases

In the differential diagnosis age is an important factor A diagnosis of thrombo angiitis obliterans may be made with some confidence in patients up to 45 years or even 50 but from 50 to 60 such a diagnosis is doubtful, and after 60 it is very unlikely A routine clinical examination should be made in all cases for evidence of arterio sclerosis and a radiogram taken of the popliteal arteries

Since calcification plays no part in thrombo angiitis obliterans the slightest evidence of arterial shadow or flecks of lime in the radiography should put the case in the arterio-sclerotic group and I have admitted no such case to my series of cases

As already mentioned the Raynaud phenomenon in the feet of a young man should arouse grave suspicion Such a case is likely before long to show thrombosis of the digital arteries and will develop into a quite definite and usually severe thrombo angiitis obliterans There is thirdly a type of case of which we have had five instances in our clinic it may be mistaken for thrombo angiitis obliterans The patients are men between 40 and 50 years of age who whilst quite unaware that they have any trouble with their legs are suddenly seized by very severe pain in the calf. The foot is stone-cold and blanched but in the course of a few days some improvement is seen walking becomes possible and the man may return to work—but the circulation in the foot does not return to normal. It seems likely that these cases are embolic in origin the embolus having been derived from some patch of atheroma or calcification in a vessel in or proximal to the popliteal. That they are not true thrombo angiitis obliterans is evident from the fact of the sudden very painful onset of pain and from the observation that the opposite leg is apparently normal.

Treatment

A mere list of the treatments which have been tried in thrombo angiitis obliterans would be of formidable length and there is little point in mentioning many of them—they have only too often fallen by the way after an introduction more optimistic than warranted by results Broadly speaking the various methods of physiotherapy are purely palliative and not without danger in limbs whose vitality is slender The production of vasodilatation by foreign proteins is also a merely temporary expedient; if these substances are used in really efficient doses the patient suffers so great a malaise that he commonly gives up the treatment after a few attempts

Two new methods at present on trial are of interest —the intravenous-saline and the negative-pressure (Pavaex) method I have no personal experience of these

There can be no doubt that in our present ignorance of the cause of the disease the operation of section of the vasoconstrictor fibres is the most reasonable Sympathectomy will produce a lasting vasodilatation in the lower extremity and if the disease has a spastic origin it should arrest its progress, but if the disease is toxic and not spastic it may nevertheless help by dilating such collateral channels as still remain healthy Obviously it will do this much better in the earlier cases than in the more advanced ones with widespread thrombosis. The varieties of sympathectomy practised have been chiefly two: (1) perivascular stripping and (2) lumbar cord ganglionectomy

Perivascular stripping has been practised by many surgeons and although it appears to be anatomically unsound it does according to the reports of reliable surgeons produce some degree of distal vasodilatation. Such a result is however both incomplete and evanescent. If an attack on the vasoconstrictor fibres is held to be good treatment surely it is better to carry out a precise and complete operation by section and removal of a portion of the lumbar ganglionated chain These considerations led Stopford and myself to decide early in 1931 that we would submit a series of cases of thrombo angiitis obliterans to lumbar cord ganglionectomy and observe the results by a very frequent follow up over a number of years.

The operation consisted of a free removal in almost every case bilateral of the lumbar ganglionated cord It is difficult to speak of definite anatomical limits because as every surgeon who has worked in this region is aware, the anatomical arrangement of these cords is subject to very wide variations. The most that one can say is that as a routine we have excised that portion which corresponds to L 2, L 3, L 4 ganglia.

The total number of patients submitted to this operation for thrombo angiitis obliterans is 112. In only 5 of these cases was the operation unilateral, and this was only because one limb had already been amputated. The remainder were all bilateral, and the ganglionectomy was carried out by transperitoneal approach under spinal anæsthesia. There has been no operation mortality in this series.

RESULTS OF LUMBAR CORD GANGLIONECTOMY

I have on two previous occasions with Prof Stopford (1933, 1935) published results of lumbar cord ganglionectomy in thrombo angiitis obliterans. These results show that in half the cases the results may be classified as "good" inasmuch as though claudication is seldom cured the walking distance has increased, rest pain has been abolished, and onychia healed and the men are back at work. In a quarter of the cases the result can only be described as "fair". These patients say they are better for the operation but the clinical improvement is not great, and this is especially true of claudication. In the remaining quarter the result is not satisfactory; some have since died and in the rest amputation has been necessary. It is, however, only fair to point out that in these patients it has been possible to carry out successfully partial amputations of feet or removal of the leg with a seven inch tibial stump whereas without the sympathectomy, amputation through the lower third of the thigh must have been done. A recent review of 98 cases confirms these previous findings.

The present inquiry is however more immediately concerned with the question as to what effect lumbar cord ganglionectomy has on the progress of the disease. If an estimate of this kind is to have any value it is essential that the diagnosis be as certain as is possible and that a sufficient length of time shall have elapsed since the operation. I have, therefore, selected only such cases as presented symptoms before 45 years of age and only such as have been operated upon since for not less than three years. The inquiry is thus confined to undoubted cases in all of whom from three to six years have elapsed since operation. The number of these is 22, all of whom have recently been seen and their present condition carefully estimated. Of the 22, 16 remain well and it is certain that the disease has made no further progress. On the other hand 6 show some degree of deterioration and display further evidences of the disease. Two show recurrent attacks of phlebitis, which suggests that a toxic factor is still at work, and 4 have required some measure of amputation, in 2 cases of toes only and in 2 others at the "site of election".

From these observations I conclude that the main and probably only benefit to be derived from lumbar cord ganglionectomy is by the dilatation of collateral paths and not by the abolition of spasm. Disappointing as this conclusion is, it does not in the least weaken my contention that, up to the present, we have in sympathectomy the most hopeful of the many treatments which have been practised for this grave and distressing disease.

THE MEDICAL TREATMENT OF NON-MALIGNANT PYLORIC STENOSIS IN ADULTS

By T Izod Bennett, M D, F R C P Lond.
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, MIDDLESEX HOSPITAL LONDON

Peptic ulceration responds well to treatment, but it is a very common condition and in spite of the success which is so often achieved there are many cases in which it is responsible for prolonged ill health and not a few in which it causes death. But it must not be assumed that the failures are the result of an imperfect method of treatment because they are often due to neglect in applying to an individual case the modifications in treatment necessary for success in that particular case. Regulation of the patient's diet is the most important of all factors in treatment, and the requirements of the individual vary so greatly that no uniform system of dietetics can be expected to secure more than a certain proportion of good results.

In a recent paper (1936) I ventured to write as follows: "It is absurd to lay down the same laws for the bank clerk, the labourer, the actor, the professional footballer, the market gardener and the society woman. Obviously the hours of activity and the food requirements of these people will vary enormously." I am convinced that the majority of the failures of medical treatment can readily be explained by neglect to meet the requirements and habits of the individual patient; there is no other disease in which the personal factor is of such great importance, and if peptic ulcer is not more successfully treated in 1937 than it was in 1927 it is because many physicians and surgeons still continue to adopt a fixed system of treatment without realising that though it may be excellent it must always require some measure of adjustment for every case to which it is applied. An extreme illustration of this has been afforded during the last two years by the transient popularity of the treatment of peptic ulcer by means of injections of histidine. With little or no evidence that this treatment had any value practitioners were persuaded to abandon nearly all dietetic precautions and to rely on a series of hypodermic injections as a method of curing this dangerous disease. The results have been so disastrous that the method is now rapidly sinking into oblivion; but it cannot be sufficiently emphasised that apart from ridiculous forms of treatment such as this a proper proportion of successes cannot be secured unless each case is judged on its merits and the diet and medicine are arranged in each case so as to secure the measure of gastric rest necessary to bring about permanent healing and health.

THE PLACE OF SURGERY

Pyloric stenosis is a complication of peptic ulceration which is usually best treated surgically. By definition a mechanical obstacle is present which must militate against the success of purely medical treatment, and it is obvious that if the obstruction could be easily remedied it would be well to relieve it in every case even if careful medical treatment were necessary afterwards. But in actual practice pyloric stenosis can seldom be relieved surgically except by a short circuiting operation or by resection of part of the stomach or duodenum, and either of these operations is very serious. Gastro enterostomy may involve only a small immediate risk, but gastro enterostomy invariably deprives the patient of that delicate control by the pylorus which is one of the fundamental functions of the stomach Gastrectomy on the other hand is always a major operation and against the fact that it often achieves the elimination of a permanently diseased area must be set the fact that it not only changes the mechanics of the stomach but deprives the patient of a considerable area of mucosa, the value of which has been revealed by all the recent work on the genesis of pernicious anæmia and kindred diseases. In spite of these considerations it remains true that pyloric stenosis usually calls for surgical treatment the classical paper of Berkman (1923) favours this view and the discussion of the subject by Eusterman and Balfour (1935) indicates surgery as the treatment although considerable attention is given to medical measures chiefly of a pre operative nature. Crohn (1927) states that the treatment is pre eminently surgical and Rehfuss (1927) is only slightly less strongly in favour of surgery

It is by no means always easy to determine whether gastric retention is the result of organic pyloric stenosis but careful X ray examination will usually suffice to eliminate those cases in which gastric atony alone is responsible Apart from loss of tonus the pyloric function may be interfered with either by disease of neighbouring structures or reflexly as the result of a large ulcer on the lesser curvature of the stomach A six hour residue in the stomach after a barium meal is the usual criterion adopted by radiologists to determine the presence of gastric retention but even when this is accompanied by evident deformity and narrowing in the pyloric region it does not necessarily follow that the pyloric stenosis is permanently of severe degree Jordan and Kiefer (1934) reported 70 cases exhibiting a six hour residue with relief obtained by medical means in 80 per cent but it must be noted that recurrence was observed in rather a high proportion of these.

CONSERVATIVE TREATMENT

Pylorospasm and œdema may temporarily transform a slight degree of obstruction into a high one but it is not my intention to deal especially with such conditions in this communication but rather to stress the fact that it is a mistake to assume that organic narrowing of the pyloric canal even of high degree must in all cases be treated surgically The following case was one of the first which directed my attention to this fact —

A. B aged 45 consulted me in 1928 He had long been known to me as a strong healthy man who complained occasionally of dyspepsia When he first asked me to see him he said he merely had a recurrence of his dyspepsia due to several indiscreet meals but as he walked about the room he was occasionally seized with attacks of severe colicky pain Physical examination revealed nothing of importance but it was clear that his symptoms were probably organic he was ordered a duodenal ulcer diet with small doses of alkali Seen in London three weeks later he told me that he had had no symptoms since the day he saw me but I advised X ray examination and this revealed pyloric stenosis with a twenty four hour residue The patient was very well and had just begun work of an *important nature which he could not postpone* He was placed on a diet from which all substances such as raw vegetables calling for prolonged gastric indigestion were excluded and was told to continue the alkali During the subsequent eight years this patient has only once had any gastric symptoms he has gained weight and has carried out his full duties without interruption Subsequent X ray examinations confirm the presence of a relatively high-grade pyloric stenosis with a gastric retention of never less than seven hours

When I first saw this patient with the X ray findings I felt that I was perhaps doing wrong in yielding to his insistence that his apparent good health and the pressing nature of his work precluded operation His subsequent history convinces me that his attitude was justified.

Shortly afterwards the following case came under my observation :—

C D attended my out patients at the Middlesex Hospital for many years When first seen at the age of 50 he was recovering from an attack of pain and vomiting which had gone on for some weeks There was a past history suggestive of duodenal ulcer and X ray examination revealed pyloric stenosis with a gastric retention of over twenty four hours He refused operation because he was already feeling nearly well, and at my suggestion returned to work on a diet which was almost entirely fluid He took bottles of milk with him to his work Seen nine months later he was re-examined with the X rays which still showed a large gastric residue at nine hours the radiograms were displayed in the out patient department and the students were asked what advice should be given to him All of them said that he must have a gastro-enterostomy I then asked the patient how he had passed the previous day and he gave a vivid description of his work as a locomotive driver on one of the big railways involving long hours of very hard work which he was carrying out with complete efficiency This work he continued to perform for many years until he died of an acute pneumonia

In this case the decision not to operate was reached at the end of three weeks preliminary treatment; in this interval the patient had been radiographed and had remained on a fluid diet and had become so well that he begged me to permit him to attempt work; he seemed a very sensible man and quite understood my explanation that even a fluid diet maintained during his work hours might fail to keep him in health. But he was determined to try this and regained strength and maintained his weight. After a few months the emptying time of the stomach had somewhat improved and the patient was perfectly happy to continue on his restricted diet.

Carcinoma of the stomach is perhaps the commonest of all causes of organic pyloric obstruction and when this condition is suspected it is usually essential to proceed to surgical treatment without delay because progressive obstruction is inevitable; but cases arise in which there is doubt as to the exact nature of the obstruction and it by no means always follows that exploration is essential. The following is an illustration :—

F F an Anglican clergyman, consulted me at the age of 69 on account of loss of appetite for two months and a feeling of distension after meals He had no pain, was well nourished and of rosy countenance A gastric analysis showed a slightly climbing curve of HCl with a considerable residue at three hours without blood or evidence of stagnation The X ray examination showed an eight hour gastric residue and the duodenal cap was practically invisible. I asked Dr R. A. Young to see him with me in consultation and we agreed that his age relative good health, and the absence of evidence of malignancy justified us in recommending purely medical treatment He was given a diet largely of fluids with small doses of alkali I did not see him again for seven years at the end of which time he consulted me for a recurrence of symptoms; he had remained well and at work for the whole period but for four weeks had been troubled with heaviness and a little pain some hours after meals and loss of appetite He was a few pounds heavier than when I had first seen him and a repetition of the examination revealed the same findings as before A few days of semi-starvation restored him to health and he has been back at work and keeping well ever since his age being now

It is worthy of remark that the three cases which have been cited had had little or no vomiting, this fact made it unnecessary to employ gastric lavage, the diet given in each case consisted of glucose lemonade for a day or two, followed by diluted milky feeds and proceeded to a semi fluid diet for several weeks The first and third patients were ultimately able to take a light diet differing little from that of other members of the household, but care was taken to avoid all foods calling for prolonged gastric digestion Sufficient attention is seldom given by medical men to the fact that perhaps the principal function of the stomach is to secure *liquefaction* of the food, recognition of this function enables us to classify the foods requiring prolonged gastric digestion with considerable exactitude, liquefaction does not connote solution, but the chyme is a thin fluid having the consistency of weak gruel. It is clear that vegetable matter, particularly raw fruits and vegetables, is the most difficult to reduce to such a state, whilst fluids such as soups, milk, cream, and soluble and semi soluble carbohydrates, such as sugar, crisp starchy products, sponge cake, and milk puddings, are the most susceptible to gastric digestion With a little care it is not very difficult to devise a sufficient and appropriate diet whenever the degree of obstruction is not insuperable, but it is very necessary to secure the willing and intelligent coöperation of the patient, and success can seldom be achieved unless the patient with pyloric stenosis realises that the diet he is given has been chosen in the not altogether optimistic hope of avoiding surgical operation The following case is instructive —

Miss G H, aged 70, was seen at a time when she was bedridden on account of vomiting and discomfort in the upper abdomen This condition had been getting worse for five weeks Appetite was good and the patient was relatively well in the morning, but was seized with vomiting in the afternoon or evening There was a history very suggestive of duodenal ulcer many years previously On examination the stomach was standing out although peristalsis was not visible After a few days' treatment X ray examination revealed gastric obstruction with a delay of over twenty four hours No actual filling defect could be seen, and the past history of mild indigestion for many years made the diagnosis of non malignant pyloric obstruction probable Surgical treatment was recommended by myself and by Mr Gordon Taylor, but the patient and her relatives were extremely reluctant to accept this She was accordingly treated by gastric lavage and a strict fluid diet, and remained well for nine months, at the end of which time vomiting recurred and was accompanied by a small hæmatemesis She was transferred to hospital and after a few days' preparation gastro-enterostomy was successfully performed She has remained well since

The vomiting and high degree of pyloric obstruction in this case made it almost certain at the outset that medical treatment could only postpone operation, and it is equally certain that without gastric lavage the patient would never have regained the brief spell of good health which preceded surgical intervention, but the fact that she had easily learnt to wash out her own stomach was of great value in that it made preparation for operation easy and safe This is of importance because prolonged vomiting will not infrequently produce a disturbance of the blood chemistry, through loss of hydrochloric acid, which profoundly affects the general condition of the patient, and may even result in attacks of tetany The dilatation of the stomach and the presence of stagnant contents present complications very unfavourable to surgical success, and these factors go far to explain the relatively inferior surgical statistics of cases with gastric retention which have been recorded by Berkman (1923)

SUMMARY AND CONCLUSION

The purpose of this paper is not in any way to suggest that medical treatment should supplant surgical treatment in cases of non malignant pyloric stenosis, but it is desirable to stress once more the fact that every case of peptic ulcer, including those with pyloric stenosis, should be treated individually Patients with a high degree of pyloric stenosis are occasionally encountered in whom health and happiness can be preserved without surgical intervention Most careful judgment is necessary in the selection and treatment of these cases

A REVIEW OF GOLD THERAPY*

By W S C Copeman, M.D Camb, M.R C.P Lond

PHYSICIAN TO THE BRITISH RED CROSS SOCIETY S CLINIC FOR RHEUMATISM LONDON AND ASSISTANT PHYSICIAN TO THE CHILDREN S DEPARTMENT OF THE WEST LONDON HOSPITAL AND

W Tegner, B M Oxon, M R C P Lond

CHIEF ASSISTANT AT THE CLINIC

Gold salts were first employed experimentally in chronic rheumatism in 1926 (Feldt) following on their previous use in pulmonary tuberculosis In 1929 Forestier published a series of cases treated by this method, claiming some success In 1932 he stated his belief that in cases of progressive rheumatoid and infective arthritis, gold was the medicament of choice Since that date we have employed gold salts in selected cases at the Red Cross Clinic and elsewhere, and this paper is an attempt to review the results in the cases that we have followed up consistently

There seems to have been no rationale for the use of gold salts in rheumatic conditions Empirical trial in the hands of some observers tended to show, however, that good results may undoubtedly be produced in certain cases of chronic rheumatism whilst in rheumatism of the juvenile type (Slot and Deville 1934) and in osteo arthritis (Weissenbach and Françon 1936) it is generally agreed that they may be harmful

It is commonly recognised now that the salts of gold, like those of most of the other heavy metals, are not without danger when used indiscriminately Amongst the "accidents" of gold therapy, those most commonly met with seem to be dermatitis, fever, diarrhœa, stomatitis, and albuminuria Although investigation of many of the reported cases suggests that most of these accidents are due to overdosage, gold being a cumulative drug there is no doubt that there are wide variations in individual susceptibility, and for this reason close observation of all cases on gold treatment becomes a very real necessity The severe general reactions culminating in temporary exacerbation of the original complaint which are not infrequently observed at the end of a course of such injections presumably differ from these 'accidents' only in degree

---

* A paper read to the Committee for the Investigation and Study of Rheumatism on Nov 3rd, 1936

Other observers (Douthwaite 1936 Pemberton 1936, Hartfall and Garland 1935) have recently reported series of cases successfully treated by means of gold salts and certain of these express the opinion that such general reactions far from being harmful are almost an essential to success This has not however been our own experience

Types Treated

Only selected cases have been treated, these all conforming unless so stated to the "rheumatoid type" of the Royal College of Physicians committee on chronic rheumatic disease (1934) Several cases of Still's disease were also treated, but are not included in the series under review (Copeman 1936). Three cases of spondylitis of the ankylosing type are however included and discussed

The present series consists of 51 cases, which is considerably less than the number treated but includes all those cases that it has proved possible to keep under periodical observation It is hoped that this series will remain under observation and will with others form the basis for a further annual survey The contra indications observed were merely those of age or obvious infirmity such as albuminuria or heart disease

Method of Treatment

In the great majority of cases the salt employed was Allochrysine, an aqueous solution of thio glyceryl-sulphonate of gold and sodium The injections were made intramuscularly into the buttock at intervals of five days in certain hospitalised cases and seven days in ambulant cases

The initial dose was in most cases 0·01 gramme progressing on the second occasion to 0·05 g and subsequently to 0·1 g which was seldom exceeded the total amount given in any series was 1·0–1·5 g This dosage is somewhat lower than that generally employed by other workers but it is thought that it is justified by the fact that although results may be slower they do ultimately appear in a remarkable proportion of cases treated, and the fact that in 51 cases we have only observed 3 accidents which could definitely be attributed to gold medication, and which proved severe enough to render further injections inadvisable None of these proved fatal. An interval of 6–8 weeks is left after the first series of injections is complete after which a further course is undertaken if the blood sedimentation rate is still raised

Before embarking upon the first series of injections the blood should be examined and if any degree of secondary anæmia is found treatment for this should be undertaken concurrently since it appears from our observations that gold tends to exacerbate and even to produce anæmia of this type After each course of injections it should again be examined if possible since as Shackle has pointed out to us a tendency towards leucopenia may sometimes be observed which in its most severe form may progress to agranulocytosis while the occurrence of eosinophilia is sometimes thought to give warning of dermatitis before this is obvious clinically

The blood sedimentation rate should also be estimated before gold injections are started and after each course This observation which is very simply performed although it is not actually diagnostic is apparently of great value in estimating the activity and so the progress of the disease It may thus be the first indication of improvement in certain cases

In our series of cases physical methods of all sorts were employed in addition to the gold therapy in order to prevent or correct mechanical deformity

Complications

A number of unpleasant sequelæ after the administration of gold salts have been reported although they have become rarer since the standard of dosage has been universally reduced for rheumatoid patients, following on the observation that this class of patient appears to be less tolerant of gold than tuberculous subjects (Secher and Gudiksen 1935) These unwanted effects fall chiefly upon the skin and mucous membranes the liver and kidneys and the hæmopoietic system. A number of fatalities have occurred, but very few of these have been published in detail. It must be assumed, however that these cases resulted from severe involvement of the latter system This is borne out by the fact that one of us was informed at the General Hospital in Vienna that in the three fatal cases seen there each had developed purpura before death It seems possible that the stages may be from purpura simplex without blood changes, through purpura hæmorrhagica to agranulocytosis and death if unchecked.

In the present series 4 cases of dermatitis were observed of which 2 were transient and of no clinical importance whilst 2 were of the exfoliative type Each of these latter cases lasted nearly three months and no form of treatment appeared to influence their course within that period In these two cases the arthritis (which had been rather overlooked during the anxious period of the dermatitis) was subsequently found to have been very much improved. The other complications observed in our series will be found in Table II and include diarrhœa general malaise stomatitis, and proctitis They occurred in 26 per cent. of the series.

It is interesting to compare Forestier and Certonciny's analysis of their recent series (1936) of 50 cases of chronic progressive polyarthritis all of 1–2 years duration before they came under treatment with gold These patients have all been observed over a minimum period of three years and had received at least four courses of gold This series they state represent their *least* satisfactory patients; the most satisfactory being those who respond after 1–2 courses of injections In this series 40 per cent showed some accident at some time none being fatal although 4 of these patients were over 70 (one aged 83 having received 0 g in all without harm!) Each course in this series averaged 1·5–3·0 g of gold The results of this prolonged therapy are expressed by the authors as follows:—

Good or very good	64%
Moderate	28
Poor or nil	8%

In Hartfall and Garland's series (1936) of 374 cases they report:—

Marked improvement or cure	77·8
Slight improvement	15%
Nil	5·8%
Worse	0·3
Died	1·3%

The complications discussed by the former authors include in addition to those already mentioned purpura jaundice which is rare but always serious pruritus eczematous patches, and herpes zoster They mention that they have never seen the arthritic condition of a patient made worse by gold although they have several times seen old troubles which they do not specify precisely exacerbated The various accidents affecting the skin and mucous membranes comprised 27 per cent of their total complications, and occurred mostly between the third and fifth courses of treatment They mention the occurrence of albuminuria also, but like Crosby (1936) agree with our own view that this sign, in the absence of symptoms or of a raised blood-urea, is of little importance and need not be an indication to interrupt the course

From a study of our cases and of those reported we believe that the contra indications for gold therapy, apart from obvious disease of the chief viscera, may be comprised practically under the headings of severe anæmia and eczema

Although it seems clear that certain persons possess a special sensitivity to gold, these are the exception and symptoms may manifest themselves even after the first injection The vast majority *of complications however do not occur until a* considerable amount of gold has been given This being so it is desirable to have some indication that "saturation point" is being approached. We believe that there is as yet no such test that is capable of routine application, although Shackle believes that a rise in the eosinophil count indicates the onset of cutaneous complications, a statement denied by Coste (1933) and Bourderon (1932) Denier (1935) has also suggested the value of infra red photography and of Wood's glass in this connexion, while Coste *regards a slight prolongation of the bleeding time* as being significant of a hæmorrhagic tendency

It is generally stated that gold may lead to a secondary anæmia and that an early manifestation of this may be a punctate basophilia Griffiths and Race (1935) found this in 16 of 21 cases investigated, although in none of our cases have we been able to confirm this observation

TREATMENT OF COMPLICATIONS

Our experience of the more severe complications of gold therapy is luckily limited. It seems, however, that prophylaxis is generally more valuable than curative treatment Dermatitis of the exfoliative type has in our experience usually lasted three months whatever treatment is employed.

Methods of prophylaxis include the routine administration of liver, calcium, and glucose It must also include reduction of dosage and the proper spacing of the injections when necessary

Methods of treatment will also include liver and calcium therapy, increase in the fluid intake, and cessation of gold injections For skin complications sodium hypophosphite may be given intravenously, 10 c cm of freshly prepared 20 per cent solution being administered daily Calcium gluconate or chloride may also be given intramuscularly in 1 per cent solution Autohæmotherapy is recommended by some authorities (Pèrles 1936) In addition to these measures a protective or anæsthetic ointment should be used, and it has seemed to us that if the affected parts can be protected from light the rash will often retrogress more quickly

Results of Treatment

A series of 51 cases has been observed and analysed over a period varying from six months to four years The results are given in the Tables The difficulty of providing a comparable control series has seemed insuperable, and this has accordingly not been attempted systematically A large number of cases of similar type have been seen during the same period, however, and treated by other methods, and our impression of the results obtained in the two series of cases is given Moreover, a considerable number of the earlier cases were given gold only as a last resort, *after all other methods had failed to check* the progress of the disease, this fact in itself is a form of control for the gold treatment *administered* subsequently

TABLE I

Duration of Disease and Amount of Treatment

—	No of cases	Apparently cured or much improved	Im proved	No improve ment
Duration—		%	%	%
Over 5 years	19	9 (48)	9 (48)	1 (4)
Under 5 years	32	20 (60)	9 (33)	3 [illegible]
Under 1 year*	14	8 (57)	6 (43)	0 (0)
Amount of gold—				
More than one course	18	13 (72)	3 (18)	2 (10)
One course or less	*33*	*15 (45)*	*16 (49)*	2 (6)

* The great majority of apparent cures fell into this group

TABLE II

Complications of Gold Treatment

Sex and age	Duration of arthritis	Type of complication	Result on arthritis
M 62	1 year	Severe exfoliative dermatitis	Arthritis cured
F 51	15 years	Diarrhœa after any dose over 0 1 g	Very much better
F 59	7 "	Malaise	Much better
F 54	9 "	*Transient rash once* ? due to gold	"
F 59	2 "	Stomatitis and proctitis	Better
F 59	2 "	Papular rash	"
F 53	6 "	Old standing diarrhœa exacerbated	"
M 51	1 year	Malaise	"
M 46	4 months	Exfoliative dermatitis and stomatitis	Apparently cured
F 38	6 years	Diarrhœa	Better

Complications occurred above the age of 50 in 80 % of cases, other cases all over 38 years All cases were improved in spite of complications

TABLE III

Effect of Treatment on Sedimentation-rate (B.S R)

Result	No of cases	Average duration of treatment	*Average fall* of B.S R (mm)
Much improved	29	5½ months	37 7
Improved	18	4 "	17
No improvement	4	5½ "	8

ANALYSIS —In this series 13 (26 per cent) were males and 38 (74 per cent) females their ages varied from twenty to sixty eight The rheumatoid type group of the Royal College of Physicians' classification included 90 per cent of the cases, 2 of which gave a previous history of gonorrhœa, 6 per cent of *cases were* of spondylitis ankylopoietica and 4 per cent of peri arthritis—that is, painful joints without conspicuous radiographic changes In 23 per cent of cases toxic symptoms were noticed during the administration of gold There were *9 per cent who received three or more courses of gold,* a course being equivalent to 1 0–1 5 g 11 per cent received two courses, 54 per cent received one course, and 26 per cent received less than one course

In the series we obtained the following results —

Great improvement or cure	58 %
Improvement	36 %
No improvement	6 %

These figures represent improvement in the *rheumatoid and peri arthritis groups, improvement* in the spondylitis cases being negligible—a point also noticed by Bach (1936)

The sedimentation rate —A study of the blood sedimentation rates (Westergren) showed that in the majority of cases (60 per cent.) there was a definite drop in the rate during and after treatment In 9 per cent. of the cases there was a preliminary rise after gold injections started which went on to a fall a point we think of importance, as a temporary *rise in the rate should not necessarily be regarded* as an indication of failure of treatment In 18 per cent. no fall was noticed and in 4 per cent. the sedimentation rate has continued to rise. Where there was a fall it corresponded with those cases that were to show a clinical improvement and it often preceded it In two cases of the series a sedimentation rate estimated some time after the last injection showed that this was rising again although subjectively the patient reported good health and no recurrence of symptoms. This probably is an indication for the continuation of small doses of gold at regular intervals, a maintenance dose being found just as in the case of liver therapy for pernicious anæmia.

Rheumatoid arthritis is known to be generally *progressive but spontaneous remissions* are known to occur although comparatively infrequently (Forestier estimates these in cases of one year's duration at 2 per cent.) Fifty-eight per cent. of cases that improved seems to be too many to be due to spontaneous remission and it would be a curious coincidence that they had all occurred during gold treatment From our figures improvement does not seem directly dependent on dosage The individual reactions of patients to gold varies very greatly however and in those cases in which severe toxic symptoms supervened a great improvement in the arthritis resulted subsequently

In certain cases an estimation of the sedimentation rate was prevented by difficulty in venepuncture which in two cases was due to a dermatitis and this would indicate the need for a reliable micro method for estimating it from the capillary blood.

Summary

1 A series of 51 cases mostly of the rheumatoid arthritic type have been treated and observed over a *period of from 6 months to 4 years* Great improvement or cure has resulted in 58 per cent The three cases of ankylosing spondylitis included in this series have shown negligible improvement only

2 Clinical improvement was preceded in a majority of the successful cases by a fall in the blood sedimentation rate In a certain proportion of these, however this fall was preceded by a preliminary rise of variable duration In no case was there clinical improvement when the sedimentation rate failed to drop In certain cases indeed the approach of *relapse was seen to be preceded by a further rise* The sedimentation rate seems therefore to be of considerable importance in the prognosis of this type of case.

3 It seems that the clinical result achieved is not always directly related to the quantity of gold administered

4 Certain accidents may result from gold therapy The importance of these seems to have been over-estimated however in recent articles Unforeseen sequelæ occurred in 23 per cent of our cases *but only in 3 cases were these so severe that the* treatment had to be discontinued. Of these three 2 were cases of exfoliative dermatitis and the other of rectal spasm hæmorrhage and stomatitis The dermatitis cases lasted in spite of treatment for about three months and their arthritis was subsequently cured ; while the latter lasted for about ten days with temporary improvement in the *arthritis which subsequently relapsed. Gold was not* recommenced in this case It seemed that albuminuria when unaccompanied by further symptoms could be discounted.

Since 11 of these 12 cases with complications occurred in ambulant patients, it seems that hospitalisation at the outset of such treatment may be desirable where this is possible.

5 When treatment was unsuccessful the period of evolution of the disease before the gold therapy has been considerably longer than the average of those cases in which it proved successful. In certain of these cases a permanent rise in the sedimentation rate curve after a preliminary fall seems to suggest that a degree of tolerance of gold may be established

6 It is our impression that gold is the medicament of choice in early cases of the rheumatoid arthritic type when the sedimentation rate is raised. It seems that its rôle is to act upon the progressive and inflammatory elements and this being so it appears to be necessary to employ physical methods *in addition to deal with the cicatricial and mechanical* aspects that remain in the majority of cases when the former elements have been controlled.

Our thanks are due to the collaboration in this work of Drs F Bach T J O Reilly A C Elkin J H. Dunn, *M. Mautner C J Berkeley Way and E Gwynne* Evans also to Drs J W Shackle and F Kellett for carrying out the pathological examinations at the Red Cross Clinic for Rheumatism and the Hospital of SS John and Elizabeth

STRIÆ ATROPHICÆ CUTIS

BY DAVID B ROSENTHAL, M.D Melb
M.R C P Lond.

MEDICAL SUPERINTENDENT OF THE GREENSWELL SANATORIUM
MONT PARK VICTORIA AUSTRALIA

ATTENTION has been directed recently to this condition by the reports from Parkes Weber (1935) *of two cases of* idiopathic striæ atrophicæ together with a brief review of other recorded cases and a summary of the causes He thought that the condition might be due to an insufficiency of cutis with perhaps a deficiency of elasticity which results in multiple cleavage to adjust to more rapidly growing parts beneath.

In an earlier report Weber (1917) recorded a case of bilateral pulmonary tuberculosis the right side being more extensively involved than the left Striæ atrophicæ were observed in the lower part of the left posterior thorax transverse to the long axis of the body This was attributed to the patient's lying usually on his left side for the skin would be stretched most in this part Siller

(1924) reported a case of striæ atrophicæ in which the lines were vertical, and limited to the regions of the arms and forearms, abdomen, and groin. Obesity, perhaps related to endocrine dysfunction, was discussed as a cause. Other factors considered were the possible disproportion between cutis and subcutis, and the rapid development of fat. A case of striæ patellaris, after enteric fever, was recorded by Rolleston (1927), who considered the abnormal trophic condition of the cutis mainly responsible, with possibly an associated increase in tension of the skin, due to the maintained flexion of the knees—a theory favoured by most authorities. The possible influence of the pituitary gland has been much discussed. The furrowing of the scalp, "which is deeply corrugated like that of a bulldog" is a well known feature of acromegaly (Boyd 1932). Here the striæ are due to redundancy of skin. In discussing such a case, Weber (1932) considered the possible relationship of pituitary disorder to the formation of idiopathic striæ, and elsewhere (1935a) suggested that in those cases of striæ associated with rapid growth at or following puberty, a temporary basophilic hyperpituitarism might be responsible. Alternatively, deficient hormonic activity of the pituitary gland might be responsible for insufficiency of cutis, leading to the formation of "vergetures" (Weber 1928)—a process somewhat akin to that seen in the hypopituitarism of Fröhlich's syndrome. It might be noted that striæ in young adolescents with obesity, which lessens or disappears with maturity and which is almost certainly due to a temporary endocrine upset, is a not unfamiliar clinical phenomenon. Goldsmith (1936) summarised the skin changes that might be associated with endocrine disorders, including the striæ albicantes (atrophicæ) of Fröhlich's syndrome, the "folding" of hyperplasia in acromegaly, and the purplish lineæ atrophicæ of Cushing's basophilic hyperpituitarism. Of this condition, Kaufmann (1929) states " The cause is an overstretching of the skin which has become less resistant. It is also thought that there may be growth asymmetry of the soft parts in relation to the growth of the bones of younger individuals, in analogy to the so called cutis verticis gyrata, a peculiar skin folding on the scalp—a consequence of incongruent disharmonic development of the scalp in relation to the underlying bones. This (occurrence of striæ) may be of practical interest in later life, as a sign of previous serious sickness." Dore (1936) remarks " The usual meaning of these lineæ is that the skin has been unduly stretched or pressed upon over some fairly long period of time, but they give no indication of the cause of the stretching. They are of a purple or livid colour at first, becoming paler in course of time. They show small cross wrinkles of epidermis at right angles to the axis of the linea, these wrinkles can be smoothed away by stretching the skin in a direction parallel to the linea, but return at once on relaxing the tension." Of particular interest in reference to the cases recorded below is the following further quotation " In pleural effusion, they (the striæ) occur in the posterolateral portion of the lower part of the thorax on the same side, whereas in unilateral pulmonary tuberculosis they are found on the opposite side, owing to the patient's lying on the unaffected part. In the semi reclining position, the skin is stretched in the lower dorsal region, and striæ occur in this part of the body."

In none of the many cases of pleurisy with effusion that have come under my observation have lineæ atrophicæ been noted, and, further, in the cases described below, it was found impossible to correlate definitely the attitude of the patient in bed with either the distribution of the pulmonary lesion, or the situation of the lineæ. The attitude appears to be determined not only by the site of the disease in the lungs, but also by subsidiary factors such as habit, inclination, or immediate surroundings.

Briefly, the causes to be considered are (1) maldevelopment insufficiency of cutis, with deficiency of elasticity, (2) rapid stretching due to tumour, obesity, growth, pregnancy, &c., (3) endocrine dyscrasia particularly pituitary abnormality, (4) toxic causes—e.g., tuberculosis, typhoid, cachectic states, &c.

From the embryology it is difficult to accept a deficiency of cutis as a primary factor, and probably the causation is multiple, the size and situation of the lineæ being determined by external physical factors, together with purely local conditions in the skin that determine the lines of cleavage.

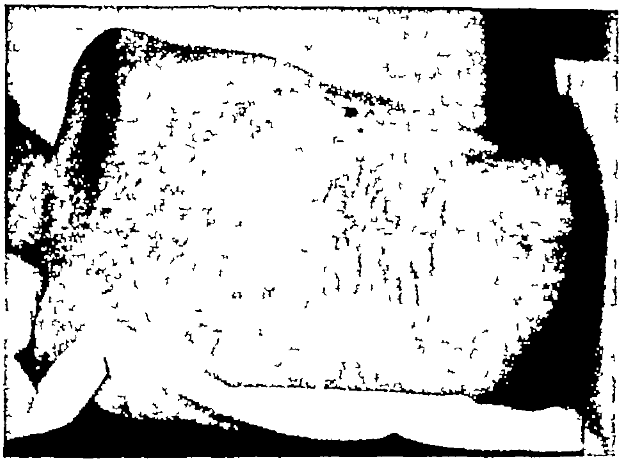

FIG. 1.—The striæ in Case 1.

A survey of a sanatorium population—in this case exclusively male—should favour the observation of such cases as are described below, pulmonary tuberculosis being a disease that pre eminently attacks young people at or about the growth period, and involves treatment that favours the development of striæ—i.e., prolonged rest. It is concluded that the tuberculous element plays little if any part in their causation.

CASE REPORTS

Case 1.—Aged 18 he was admitted in May, 1935, suffering from unilateral tuberculosis of the right lung. Treatment included a long period of rest in bed, and later pneumothorax therapy. In October striæ were first noticed on the back, over the dorsolumbar region, both sides of the body being involved, but the distribution slightly favouring the right side. The striæ were roughly transverse to the long axis of the body, as a photograph taken at this time clearly shows (Fig. 1). No increase in number was noticed, whilst the colour gradually faded from the initial purplish red, through a stage of pale pink in April, 1936, to ill-defined white streaks in June, 1936. When examined in August the original striæ could be recognised only with difficulty. General condition was good throughout.

There was a history of rapid growth at the age of 15. His height was 6 ft. 1 in. when first seen, and remained unchanged during the period of observation. His weight was 10 st. 1 lb. in December 1934, 8 st. 7 lb. in December, 1935, and had gradually increased again to reach 9 st. in August, 1936. The patient preferred no particular position when at rest in bed.

He volunteered the information that he had indulged to a considerable extent in bicycle racing during the years 1933 to 1935, and it is suggested that the maintenance of the attitude of full spinal flexion that this exercise demands may have helped to determine the site, if not the occurrence, of the striæ.

Case 2.—Aged 18 he was admitted in August, 193 suffering from bilateral disease the left lung being the more affected. His height was 6 ft and his weight 9 st 3 lb. Early in 1936 lineæ atrophicæ were observed in the dorsolumbar region similar to those in the previous case but forming four discontinuous linear markings to the left of the midline. They showed well the cross-wrinkling at right angles to the line of the lineæ described by Dore. Little change has been noted in their appearance up to the present time.

This patient emphatically preferred the right side when lying in which position the affected portion of skin was not stretched, but rather folded the striæ falling naturally into the sulci so produced. More recently it was noted that the skin over the left clavicular region, where muscular wasting was pronounced, had a slight folding the lineæ being roughly parallel to the clavicle.

General condition was poor with progressive emaciation.

CASE 3.—Aged 16 years admitted in January, 1936 suffering from bilateral disease of chronic type both lungs being about equally involved. Weight 7 st 9 lb height was 6 ft. Great improvement from the beginning of routine treatment with increase in weight. In July when the weight was 10 st striæ atrophicæ were noticed on the buttocks and thighs, symmetrical in distribution the direction on the anterior surface of the thighs being roughly at right angles to the long axis of the limbs whilst the striæ on the posterior surface were along the axis. Those on the buttocks tended to radiate from the coccygeal region. The striæ were linear and red and similar to those seen on the abdominal wall in pregnancy and were associated with the development of fat in the same region. A few weeks later there appeared one linea in the lower dorsal region in a direction transverse to the long axis of the body. It was mainly right-sided but crossed the midline. The length was 63 mm and the width at the broadest part was 4 mm. The colour was deep red with a covering of thin "papery" epidermis. The appearance was as of a cleavage in the subepidermal tissues.

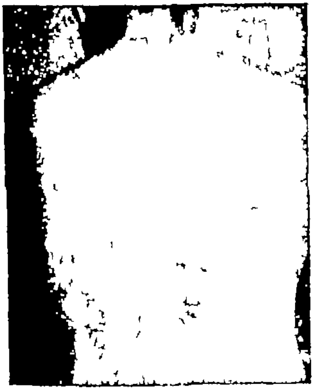

FIG. 2 (Case 4).—The striæ when fully developed

This patient lay mainly on his back, with a slight preference for the right side. His weight in August was 10 st 9 lb whilst his height was unchanged at 6 ft.

There was much to suggest a pituitary abnormality in this case: relative obesity with fat distribution rather of the female type, thighs buttocks, and breasts being particularly affected a full fat face; voice tended to be rather high pitched; and the limbs were somewhat disproportionally long. On the other hand the mental state was normal the external genitals appeared to be normally developed and X ray examination of the skull showed a normal pituitary fossa.

CASE 4.—Aged 22 years he came under observation suffering from bilateral disease the right lung being affected more than the left. His height was 5 ft 11 in and his weight, which a year before had been 11 st 7 lb., was 9 st 5 lb. About a month after admission striæ atrophicæ were seen in the dorsolumbar region, similar in type to those described above one lineæ occurred on the right side and three on the left. About two weeks later several lineæ shorter and less clearly defined had appeared on the right side whilst those previously seen were already fading. The striæ have now developed to the extent shown in Fig 2. The general condition was poor but improving. The patient preferred lying on the right side.

The cases here described have several features in common. The patients were all young men at or just past the growth period. They were all suffering from uncomplicated pulmonary tuberculosis. No symptoms were referable to the skin condition which was discovered during routine examination. In each case the blood gave no reaction to the Wassermann test.

One other case illustrating the somewhat similar condition of macular atrophy has been observed. The region affected was a roughly circular area of skin, overlying the lower dorsal spine in the midline and about 10 cm. in diameter. The macules were quite white and dull. The skin was somewhat dry but otherwise normal. This patient (who was unaware of the condition) was aged 26 his height was 6 ft and his weight, which had reached 12 st was just under 10 st.

THE SITE OF THE PULMONARY LESION AND THE ATTITUDE OF THE PATIENT

In order to ascertain whether the site of the lung disease influenced the position in which the patient reclined at rest a questionnaire was circulated amongst 100 sanatorium patients. The results of this investigation, together with the site of the lung lesion as determined by clinical and X ray examination are shown in the Table. It was difficult to draw any definite conclusions but it will be noted that in the unilateral group the right side was favoured in reclining although the majority of unilateral lesions were right-sided. Although some patients asserted that certain postures aggravated the cough (as would be expected) most were unable to give any reason for attitude at rest other than that they had always slept that way. In 3 cases only did the patient state that the onset of the illness had determined any alteration of the position of rest.

Results of Questionnaire in 100 Sanatorium Patients

Site of lung lesion	Position of rest				Total.
	Right.	Left	Indiff	Back.	
Unilateral—					
Right	11	9	2	2	24
Left	10	1	4	—	15
Bilateral—					
Approx equal	11	4	8	—	23
Right more than left	9	1	3	—	13
Left more than right.	10	3	5	—	18
Pleurisy with effusion—					
Right	2	1	—	—	3
Left	1	—	1	—	2
Bilateral	1	—	—	1	2
Total	55	19	23	3	100

SUMMARY

1 Four cases of striæ atrophicæ, observed in young men suffering from pulmonary tuberculosis are reported, with brief mention of one case of macular atrophy.

2 In one of these cases evidence of disordered pituitary function was observed

3 In determining the site of the striæ the reclining posture was of uncertain significance.

4 Tuberculosis has little if any effect in their causation

I wish to acknowledge my thanks to the matron of the Gresswell Sanatorium, who was responsible for the arrangement of the questionnaire and to Dr J Bell Ferguson, State Director of Tuberculosis, Victoria, for permission to publish the records of these cases

THE TRYPTOPHANE REACTION IN THE CEREBRO-SPINAL FLUID

ITS VALUE IN THE DIAGNOSIS OF TUBERCULOUS MENINGITIS

By John Spillane, M B Wales, M R C.P Lond

JUNIOR ASSISTANT TO THE MEDICAL UNIT WELSH NATIONAL SCHOOL OF MEDICINE THE ROYAL INFIRMARY, CARDIFF

Examination of the cerebro spinal fluid is an important procedure in the diagnosis of tuberculous meningitis The presence of the tubercle bacillus is, of course, conclusive, but its successful demonstration varies with different workers Péhu, Dufourt, and Lafarcinade record a positive result in only 27 per cent of their series, whereas Hemenway (1911) and others claim success in 100 per cent In a consecutive series of 80 cases Ingham (1936) found the bacillus in 78 The successful demonstration of the organism, however, often demands very prolonged search and the chances of success often vary with the length of time expended Occasionally a positive result is obtained only after three or four hours at the microscope Such an inordinate expenditure of time is often impracticable, and so the attention of workers has been directed to other methods of examining the fluid with the object of discovering some specific reaction, easy of application and less time consuming, of these, the demonstration of tryptophane bodies seems the most promising

In 1927 Aiello directed attention to the presence of tryptophane bodies in the cerebro-spinal fluid (C S F) of cases of tuberculous meningitis and obtained a positive result in over 90 per cent of cases investigated No true positive results were obtained in other conditions, and he concluded that a negative reaction practically excludes the disease Brugi (1923) obtained a positive result in each of 12 cases of tuberculous meningitis, and no true positive result in 30 other conditions Lichtenberg (1932) applied the test to the C S F from 78 children and obtained positive results in 25, all of whom had tuberculous meningitis in 23 the clinical diagnosis being confirmed by finding the bacilli in the fluid either before or after death, the remaining 2 cases died but autopsy was refused, though there was no doubt about the diagnosis Among the 53 negative fluids no case of tuberculous meningitis was discovered Rosenblatt (1934) obtained positive reactions in 12 cases of tuberculous meningitis, and a control group of 45 fluids from various other conditions gave no true positive results Schumacher (1934) obtained 100 per cent positive results in 32 cases of the disease In a control series of 82 specimens one true positive reaction was given—a case of cerebral tumour In a series of 19 cases of tuberculous meningitis, Bock (1936) found the test positive in each In a control series of 97 clear fluids from other conditions he obtained negative reactions, and 3 purulent fluids (2 meningococcal and 1 staphylococcal meningitis) gave 'false positive" results

All the above investigators found that "false positive" reactions occurred in purulent, hæmorrhagic or xanthochromic fluids regardless of cause, and concluded that the test is only applicable to *clear* fluids Inasmuch as the C S F in tuberculous meningitis is usually clear the test is not thus invalidated.

THE TEST

Three reagents are required (1) Hydrochloric acid, concentrated (2) Formaldehyde, 2 per cent aqueous solution, prepared fresh daily by making a 1 in 20 dilution of the stock 40 per cent formaldehyde (3) Sodium nitrite, 0 06 per cent aqueous solution, a 0 6 per cent stock solution should be prepared weekly and from this a dilution of 1 in 10 made at the time of examination Take 3 c cm of C S.F in a test-tube, add 15 c cm of the concentrated hydrochloric acid and 2 or 3 drops of the 2 per cent formaldehyde solution Shake and allow to stand for five minutes Gently float on 2 c cm of the sodium nitrite solution and again allow to stand

A positive reaction appears in two or three minutes as a delicate violet ring at the junction of the floating sodium nitrite solution with the subjacent fluid and persists for 15–30 mins or more The reaction is negative if no change occurs or only a faint yellowish ring appears at the junction The reaction is best observed by daylight against a white background Its intensity is in some measure quantitative, often being greater in well developed cases and increasing as the illness progresses In early cases the colour change is often delicate and especial care is necessary for its observation The whole test, including the preparation of fresh solutions, can be carried out in 20 mins and expert knowledge is not required.

The "false positive" reaction, which is only obtained in purulent, hæmorrhagic, or xanthochromic fluids irrespective of their cause, appears as a purplish ring at the fluid junction, deeper in colour, thicker and more easily seen than the true reaction, and in many cases diffusing into the fluids both above and below

RESULTS OF THE TEST

The C S F from 172 consecutive cases of various diseases have been studied.

In 29 the fluids were purulent, hæmorrhagic, or xanthochromic and so were considered unsuitable for the test, on examination they gave, as was to be expected, a "false positive" reaction Of these there were 13 purulent fluids obtained from *meningococcal meningitis* (10 cases) pneumococcal meningitis (1 case), influenzal (Pfeiffer s bacillus) meningitis (1 case), and streptococcal meningitis (1 case), 5 were hæmorrhagic fluids from cerebral hæmorrhage (3 cases) and subarachnoid hæmorrhage (2 cases), and 11 were xanthochromic fluids, subarachnoid hæmorrhage (5 cases), spinal tumour (4 cases), and tabes dorsalis (2 cases)

There remained 143 fluids which, being clear, were suitable for applying the test The following results were obtained —

Of 32 cases of tuberculous meningitis, all but one were confirmed by demonstrating the bacilli in the fluid, 30 gave a positive tryptophane reaction and 2 a negative. The negative fluids in other respects were typical of tuberculous meningitis The first, from a baby aged

12 months, on the seventh day of the illness showed 68 cells (chiefly lymphocytes) per c.mm chlorides 510 mg per 100 c cm proteins 70 mg per 100 c cm ; and sugar 45 mg per 100 c cm The second, from a girl aged 6 on the fourteenth day of the illness had a cell count of 109 (chiefly lymphocytes) per c mm chlorides, 620 mg per 100 c.cm ; proteins 50 mg per 100 c.cm and sugar 40 mg per 100 c.cm In each case the tubercle bacillus was found after a search of roughly 15 mins.

Two of the positive cases are worthy of special mention.

CASE 1—A boy aged 14 had been suffering for one month from miliary tuberculosis of the lungs There were no signs of involvement of the nervous system and the C.S.F was clear and normal cytologically and chemically The tryptophane reaction proved negative The patient developed signs of meningitis—neck rigidity Kernig's sign, &c.—48 hours after examination of the fluid At this stage examination of the fluid revealed an increased cellular content some diminution in the chlorides and sugar but no tubercle bacilli even after searching for several hours The tryptophane reaction was now clearly positive

CASE 2—A boy aged 15 also with miliary tuberculosis of the lungs but no evidence of involvement of the nervous system, had been ill for 3 days when lumbar puncture revealed a clear and normal cerebro-spinal fluid No tubercle bacilli could be found after prolonged search and the tryptophane reaction was negative Three days later symptoms of meningitis appeared and examination of the fluid showed a greatly increased cell count, a high protein content and diminished chlorides and sugar Tubercle bacilli were demonstrable and the tryptophane test was now positive

There were 25 cases of tuberculosis (bones joints and chests) without involvement of the nervous system all of which gave a negative tryptophane reaction. In each of 61 cases of nervous diseases, other than tuberculosis of the meninges, brain or cord the fluid gave a negative reaction, the pathological conditions in these cases being as follows :—

Meningismus (6) acute aseptic meningitis (1) ; cerebral abscess (3) ; cerebral tumour (5) disseminated sclerosis (8) general paralysis (8) cerebral syphilis (4) ; tabetic optic atrophy (1) ; tabes dorsalis (4) ; epidemic encephalitis (1) ; idiopathic epilepsy (2) congenital syphilis (1) transverse myelitis (1) spinal tumour (1) ; dementia præcox (10) ; manic-depressive psychosis (5)

Finally the C S F from 25 cases which was normal in every respect—cells proteins chlorides and sugar—and from persons showing no evidence of tuberculosis or any disease of the nervous system gave without exception a negative tryptophane reaction.

THEORY OF THE REACTION

The chemistry of the reaction is unknown but Aiello suggests that it is due to the presence of free tryptophane that has been separated from the fibrin in the C S.F by the action of autolytic enzymes A consideration of the work of Fildes and Knight (1933) on the relation of tryptophane to the growth of bacteria may be of some significance They have shown that tryptophane is essential for the growth of certain bacteria in vitro whereas others will grow in media which contain none ; the latter they consider are able to synthesise tryptophane Examining a culture of human tubercle bacilli which for years had grown in the absence of tryptophane they found the substance in the bacterial bodies and therefore concluded that this organism can synthesise it In view of these findings therefore one might put forward the tentative suggestion that the tryptophane reaction in the clear cerebro-spinal fluid from cases of tuberculous meningitis depends upon the presence of tubercle bacilli in that fluid

SUMMARY AND CONCLUSIONS

An account of the tryptophane reaction in the cerebro-spinal fluid is given. The whole test can be performed in 20 mins It is suggested that the tryptophane is synthesised by tubercle bacilli in the fluid. *The test is inapplicable in purulent, hæmorrhagic, or xanthochromic fluids*—a "false positive" reaction being given. In all, the C S F from 172 consecutive cases of various diseases was studied In 30 out of 32 cases of tuberculous meningitis the reaction was positive. In all the remaining 111 clear fluids the test proved negative

In a clear cerebro spinal fluid, therefore, a positive tryptophane reaction is highly characteristic of tuberculous meningitis

I am indebted to Prof A M Kennedy for his help in the preparation of this paper

ANÆSTHESIA FOR INTRACRANIAL OPERATION

A NEW TECHNIQUE

By PHILIP AYRE, M R C S Eng
ANÆSTHETIST TO ROYAL VICTORIA INFIRMARY AND NEWCASTLE GENERAL HOSPITAL AND HON ANÆSTHETIST TO BABIES HOSPITAL, NEWCASTLE UPON-TYNE

THE greatest bugbear of the neurological surgeon is vascular oozing which may so obscure the field of operation as to render his task difficult or even impossible. In anæsthesia for intracranial operations it is the imperative duty of the anæsthetist to employ a technique whereby congestion and vascular oozing are reduced to a minimum.

At the present time three methods are commonly used :

(*a*) Local infiltration with Novocain only
(*b*) Basal anæsthesia with Avertin combined with local infiltration ; and
(*c*) Nitrous oxide and oxygen administered by the endotracheal technique

Of these three methods the first is undoubtedly the best, but the mental strain is too great for most patients and many surgeons. The second method is quiet and relatively free from vascular congestion so long as the airway is kept free—not always an easy matter It has the disadvantage that the basal anæsthetic may wear off before the operation is finished, in which case general anæsthesia has to be administered in addition There is also real danger that an unexpected severe hæmorrhage may so deplete the patient's vitality that a light basal narcosis suddenly becomes transformed into a dangerously deep coma and the anæsthetist can do very little about it In any case the respiratory and other vital medullary centres may already be depressed by intracranial disease and I prefer to employ light premedication such as Omnopon gr ¼ with scopolamine gr 1/150, or atropine gr 1/120 an hour before operation

The third method, endotracheal nitrous oxide and oxygen, has the very great advantage that perfect control may be exercised over the patient, while maintaining a light stage of anæsthesia Indeed, Magill's inhalational endotracheal technique represents the greatest advance made in anæsthetic technique during the present century Unfortunately, nitrous oxide administered by the "closed" technique always creates a certain amount of vascular congestion, even with the most skilful administration this congestion may be negligible in general surgical procedures, but in an intracranial operation the resultant vascular oozing may seriously interfere with the success of the operation, besides endangering the life of the patient

The ideal medium for intracranial anæsthesia s, in my opinion, the Magill wide bore endotracheal tube, while the *circuit should be open to the outside* air, in order to reduce congestion to the minimum The following method devised by myself provides what is virtually "open" anæsthesia, without any rebreathng bag, expiratory valve, or other obstruction to free respiration By this method the patient breathes ordinary fresh air, supplemented by a continuous flow of oxygen at the rate of three or four litres a minute, to which is added the minimal amount of ether or chloroform vapour to maintain anæsthesia

The apparatus required is very simple, and consists of a metal T piece connected by a short piece of rubber tubing and a metal angle piece, to a Magill endotracheal tube (Fig 1) One limb of the T piece is connected to Boyle's or any apparatus delivering a continuous flow of oxygen with ether or chloroform vapour The other limb s open to the outside air, and forms an outlet through which to and fro respiration takes place To obtain the best results, a length of rubber tubing not less than one centimetre in inside diameter should be attached to the outlet, this may be attached by means of adhesive strapping to some convenient part of the anæsthetic table A thin piece of gauze, similarly attached near the open end of the tube, will be blown to and fro by the patient's respirations, thus serving as a useful indicator to the anæsthetist

The principle is similar to the Clausen Evans airway for intrapharyngeal anæsthesia In theory, the tubing attached to the outlet forms an obstruction to respiration, but, in practice, this appears to be of no significance Indeed, the quietness of respiration and absence of vascular congestion resulting from the T-piece technique have been a revelation to myself and others who have witnessed it The objection that chloroform and ether are toxic agents is also not borne out in clinical practice, patients anæsthetised by this method make an exceptionally good post operative recovery, and less shock is seen at the end of a long operation than when nitrous oxide and oxygen have been administered The reason is not far to seek With the T piece method the patient has free communication with the outside air, and is consequently able to breathe under practically normal physiological conditions throughout the longest operation Lastly, and perhaps most important of all, the relative absence of vascular oozing ensures that the patient loses as little blood as possible

CASE REPORTS

The following are the accounts of three intracranial operations on patients anæsthetised by the T piece technique, two of these were consecutive

CASE 1 —A woman aged 38 Operation (Dec 24th) extirpation of adenoma of pituitary gland Premedication atropine gr 1/120 an hour before operation Induction evipan sodium 4 c cm followed by gas-oxygen ether Subsequent anæsthesia oral intubation with size 8 Magill tube Oxygen with minimal chloroform by T piece technique for 50 minutes, while diathermy was being used Oxygen with minimal ether during remainder of operation

Remarks —Despite the fact that she was a big, obese woman, the operative field was remarkably free from vascular congestion The tumour was enucleated without difficulty, the operation being completed in 2 hrs 10 mins At the end the blood pressure was only 3 mm lower than at the start, her colour was excellent, and there was no sweating or pallor The respiratory rate remained constant throughout The pulse rate was rapid, but not unduly so considering the magnitude of the operation (Fig 2)

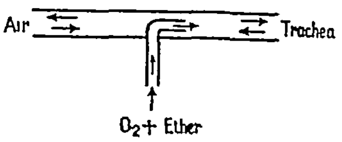

FIG 1.—The T piece

Progress —She recovered consciousness less than an hour after operation, vomited once, very slightly Next morning she was bright and well the nursing staff were emphatic that her general condition was better than in other similar cases Subsequent recovery was uninterrupted and without complications

CASE 2 —A youth aged 19 Dec 23rd: section of sensory root of fifth nerve for pain in area of distribution of the left trigeminal nerve, after tooth extraction some months before, and complicated by what was thought to be a carcinoma involving the temporal bone Premedication omnopon gr ⅓ with atropine gr 1/120 an hour before operation Induction evipan sodium 6 c cm followed by gas-oxygen ether Subsequent anæsthesia nasal intubation by "blind" method, a size 7 Magill tube being used Oxygen with minimal chloroform administered by T piece technique throughout operation

Remarks —On opening the left middle fossa extensive carcinomatous growth was found The tumour had broken through the temporal bone and was so widespread that operation by this route had to be abandoned After closing the opening he was turned over on to his face and the posterior fossa explored The operative field was unusually dry and the sensory root of the fifth nerve was exposed and divided with ease At the end of the operation which took three hours, his general condition was very good The chart readings remained at a constant level, except during the period between the two operations, when he was being turned over on to his face (Fig 3)

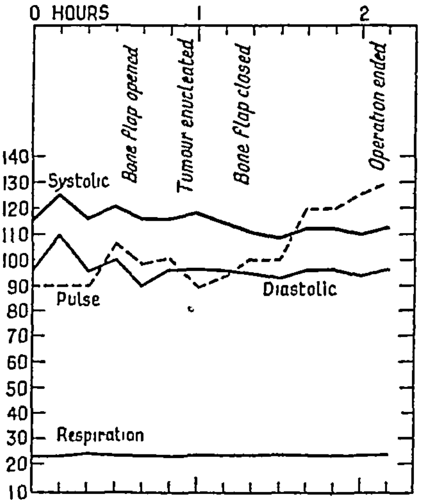

FIG 2 (Case 1) —Operation chart showing blood pressure pulse and respiration rate during intracranial operation

Progress —He was able to talk rationally half an hour after the operation He vomited once only, and subse quent recovery was uneventful Naturally the ultimate prognosis is bad.

CASE 3 —Another patient with trigeminal neuralgia was operated upon (through the middle fossa) in a similarly successful manner The patient was a thick necked purple-faced man of 74, of the type that usually puts up a strenuous resistance to general anæsthesia He was induced with evipan sodium and a little chloroform on an open mask. The operation lasted two hours during which 2 drachms of chloroform were given by the T-piece This was rather less than the amount usually required This patient gave no trouble whatsoever and was sitting up in bed next morning reading the paper Ten days later he was discharged from hospital completely cured

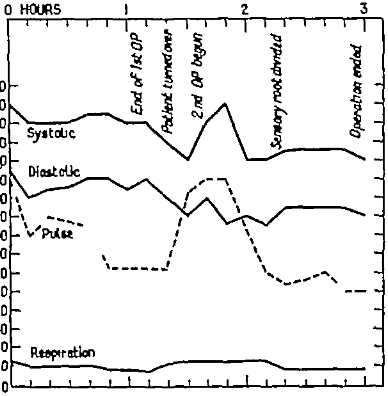

FIG 3 (Case 2) —Operation chart during intracranial operation

OTHER APPLICATIONS

The T piece technique may also be employed as an alternative method of endotracheal anæsthesia in other surgical operations, when closed gas-oxygen anæsthesia is contra-indicated. It is especially valuable in operations for repair of hare lip or cleft palate in newly born babies and young children Oxygen with minimal ether is administered and the excellent colour and easy respirations compare most favourably with the ashy grey pallor and rapid breathing sometimes seen when nitrous oxide is administered to young babies

CONCLUSION

I do not suggest that chloroform or ether should replace nitrous oxide-oxygen for routine anæsthesia The non toxic properties of nitrous oxide render it a most valuable anæsthetic agent *so long as it is reserved for suitable cases* After all it is the duty of the anæsthetist to adapt the anæsthetic to the patient not the patient to the anæsthetic and there are occasions when long continued anoxæmia may ultimately harm the patient more than the very slight toxic effects of a competently administered ether or chloroform anæsthetic. Cyclopropane is outside the scope of this article since it is quite unsuitable for intracranial anæsthesia Vinyl ether is a possibility but is still in the experimental stage

I am greatly indebted to Mr A. R. D Pattison neurological surgeon to the Newcastle General Hospital and the Sunderland Corporation for allowing me to publish the case record A special T piece as described in the foregoing paper may be obtained in two sizes from Messrs A Charles King 34 Devonshire-street, London W

Clinical and Laboratory Notes

VITAMIN B_1 AND DIPHTHERIA

BY B A PETERS M.D Camb D.P H
MEDICAL SUPERINTENDENT TO THE HAM GREEN HOSPITAL, BRISTOL AND
R N CUNNINGHAM M.Sc Ph.D Lond A I C
RESEARCH BIOCHEMIST AT THE HOSPITAL

THE clinical resemblance between the late stages of diphtheria poisoning and beri beri is very obvious as both show anorexia circulatory failure and poly neuritis On the supposition that the diphtheria toxin might destroy vitamin B_1 in the organism feeding experiments with vitamin B_1 concentrates were employed in this hospital in 1931 during convalescence but the results showed that the vitamin B_1 given in this form had no effect on this condition Russell (1930) showed that in cases of polyneuritis due to other causes the parenteral administration of vitamin B_1 concentrates was successful in curing the condition although giving it by mouth was unsuccessful The work of Prof. Peters and his colleagues (1936) showed that vitamin B_1 was concerned in the later oxidation changes of glucose and if this vitamin was deficient an increase of pyruvic acid could be demonstrated in the tissues and blood of experimental animals

On these grounds we considered that a further investigation on these points might be of value especially as Hector (1926) working in this hospital, showed there was a considerable defect in the storage and the ability of the tissues to utilise glucose in diphtheria. We therefore carried out a series of experiments on animals and a clinical investigation

ANIMAL EXPERIMENTS

One series of analyses was carried out on normal guinea pigs bled to death. Another series of guinea pigs was given 4 minimum lethal doses (m.l.d) of diphtheria toxin (kindly supplied by Dr R A O Brien) and estimations of pyruvic acid were made on the blood taken shortly before death

For the pyruvate determinations blood was deproteinised by precipitation with trichloroacetic acid (Thompson and Johnson 1935) and pyruvic acid estimated in the filtrate colorimetrically by the 2 4-dinitrophenyl hydrazone method (Peters and Thompson 1934)

We then attempted to produce the chronic form of the disease by giving 4–12 m l.d. followed four hours later by 750 units of concentrated antitoxin, which prevented death in the animals given not more than 4 m l.d of toxin recovery taking place slowly The survivors showed no polyneuritis one of these was bled after 14 days and the pyruvate estimated. The results are given in the Table

Pyruvic Acid (mg per 100 g blood)

Normal animals	Animal given 4 m l d toxin	Animal given toxin + antitoxin
3 18	2 45	4 31 (1* m l d toxin)
3 11	2 10	3 31
3·03		3 16 (4 m l d toxin)

Figures from the injected animals showed no appreciable deviation from the normal figures

The heart and leg muscles of some of both the normal and infected animals were tested qualitatively with scopolamine gr 1/150, or atropine gr 1/120 an hour before operation

The third method, endotracheal nitrous oxide and oxygen, has the very great advantage that perfect control may be exercised over the patient, while maintaining a light stage of anæsthesia Indeed, Magill's inhalational endotracheal technique represents the greatest advance made in anæsthetic technique during the present century Unfortunately, nitrous oxide administered by the "closed" technique always creates a certain amount of vascular congestion, even with the most skilful administration this congestion may be negligible in general surgical procedures, but in an intracranial operation the resultant vascular oozing may seriously interfere with the success of the operation, besides endangering the life of the patient

The ideal medium for intracranial anæsthesia is, in my opinion the Magill wide bore endotracheal tube, while *the circuit should be open to the outside air*, in order to reduce congestion to the minimum The following method devised by myself provides what is virtually "open" anæsthesia, without any rebreathing bag, expiratory valve, or other obstruction to free respiration By this method the patient breathes ordinary fresh air, supplemented by a continuous flow of oxygen at the rate of three or four litres a minute, to which is added the minimal amount of ether or chloroform vapour to maintain anæsthesia

The apparatus required is very simple, and consists of a metal T piece connected by a short piece of rubber tubing and a metal angle piece, to a Magill endotracheal tube (Fig 1) One limb of the T piece is connected to Boyle's or any apparatus delivering a continuous flow of oxygen with ether or chloroform vapour The other limb is open to the outside air, and forms an outlet through which to and fro respiration takes place To obtain the best results a length of rubber tubing not less than one centimetre in inside diameter should be attached to the outlet this may be attached by means of adhesive strapping to some convenient part of the anæsthetic table A thin piece of gauze, similarly attached near the open end of the tube, will be blown to and fro by the patient's respirations, thus serving as a useful indicator to the anæsthetist

The principle is similar to the Clausen Evans air way for intrapharyngeal anæsthesia In theory, the tubing attached to the outlet forms an obstruction to respiration, but, in practice, this appears to be of no significance Indeed, the quietness of respiration and absence of vascular congestion resulting from the T piece technique have been a revelation to myself and others who have witnessed it The objection that chloroform and ether are toxic agents is also not borne out in clinical practice, patients anæsthetised by this method make an exceptionally good post-operative recovery, and less shock is seen at the end of a long operation than when nitrous oxide and oxygen have been administered The reason is not far to seek With the T piece method the patient has free communication with the outside air, and is consequently able to breathe under practically normal physiological conditions throughout the longest operation Lastly, and perhaps most important of all, the relative absence of vascular oozing ensures that the patient loses as little blood as possible

Clinical and Laboratory Notes

VITAMIN B_1 AND DIPHTHERIA

BY B A. PETERS M.D Camb D.P H
MEDICAL SUPERINTENDENT TO THE HAM GREEN HOSPITAL, BRISTOL AND

R. N CUNNINGHAM M Sc Ph D Lond. A I C
RESEARCH BIOCHEMIST AT THE HOSPITAL

THE clinical resemblance between the late stages of diphtheria poisoning and beri beri is very obvious as both show anorexia circulatory failure and poly neuritis On the supposition that the diphtheria toxin might destroy vitamin B_1 in the organism feeding experiments with vitamin B_1 concentrates were employed in this hospital in 1931 during convalescence but the results showed that the vitamin B_1 given in this form had no effect on this condition Russell (1936) showed that in cases of polyneuritis due to other causes the parenteral administration of vitamin B_1 concentrates was successful in curing the condition, although giving it by mouth was unsuccessful. The work of Prof. Peters and his colleagues (1936) showed that vitamin B_1 was concerned in the later oxidation changes of glucose and if this vitamin was deficient, an increase of pyruvic acid could be demonstrated in the tissues and blood of experimental animals

On these grounds we considered that a further investigation on these points might be of value especially as Hector (1926), working in this hospital showed there was a considerable defect in the storage and the ability of the tissues to utilise glucose in diphtheria We therefore carried out a series of experiments on animals and a clinical investigation

ANIMAL EXPERIMENTS

One series of analyses was carried out on normal guinea pigs bled to death Another series of guinea pigs was given 4 minimum lethal doses (m.l.d) of diphtheria toxin (kindly supplied by Dr R. A O Brien) and estimations of pyruvic acid were made on the blood taken shortly before death

For the pyruvate determinations blood was deproteinised by precipitation with trichloroacetic acid (Thompson and Johnson 1935) and pyruvic acid estimated in the filtrate colorimetrically by the 2 4-dinitrophenyl hydrazone method (Peters and Thompson 1934)

We then attempted to produce the chronic form of the disease by giving 4–12 m l.d followed four hours later by 750 units of concentrated antitoxin which prevented death in the animals given not more than 4 m l.d. of toxin recovery taking place slowly The survivors showed no polyneuritis one of these was bled after 14 days and the pyruvate estimated The results are given in the Table

Pyruvic Acid (mg per 100 g blood)

Normal animals	Animal given 4 m.l d toxin	Animals given toxin + antitoxin
3·19	3·45	4·34 (12 m l d toxin)
3·11	2·40	3·34 ,,
3·63		3·1 (4 m l d toxin)

Figures from the infected animals showed no appreciable deviation from the normal figures

The heart and leg muscles of some of both the normal and infected animals were tested qualitatively for pyruvate by means of sodium nitroprusside (Case and Cook 1931) Except in one or two isolated cases, the reaction was always negative

CLINICAL EXPERIMENTS

Examination of the bloods of two normal persons and two severe cases of diphtheria suffering from paralytic sequelæ were also examined, the results were —

	Mg pyruvic acid per 100 g blood	
Normal	1·05	1 26
Paralysis cases	1 44	2 18

Again no considerable alteration from the normal was shown

A series of 10 severe cases of diphtheria was given sub cutem daily doses of 560 units of vitamin B_1 concentrate (Roche Products Ltd) from the seventh to the twenty eighth day of disease This treatment had no effect on the incidence of paralysis, as two had paralysis of the palate and ciliary muscles and two others showed an additional paralysis of the pharynx and diaphragm, both of which terminated fatally—one after a week in a Drinker respirator and the other very suddenly

CONCLUSIONS

It is thus obvious from the experimental and clinical results that the stage of glycolysis in which vitamin B_1 is concerned is not affected by the diphtheria toxin and no benefit arises in this condition from its administration

We are indebted to the Sir Halley Stewart Trust for grants towards the expenses of this work, to Dr D M Stone and Dr R T Cooke, of the Department of Preventive Medicine, Canynge Hall, Bristol, for carrying out the injections on the guinea pigs and to Mr F E Needs, *Bristol city analyst, for* allowing us working space in his laboratories

OSTEOMYELITIS

BY WALTER BROADBENT, M D Camb , F R C P Lond
CONSULTING PHYSICIAN TO THE ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON

OSTEOMYELITIS is a fulminating disease, which nearly always starts in an epiphysis Since the epiphysis is near a joint, it may be mistaken for rheumatic fever with disastrous results I have in past years seen in consultation two fatal cases of purulent pericarditis due to this error In one, a boy of 15, the lower epiphysis of the femur was involved, and it should have been easy to diagnose, as the swelling was all above the knee joint In the other, a child of 3, the osteomyelitis had started in the upper epiphysis of the femur, and must have been obscure at first, though it was clear when I saw it, there being a fluctuating swelling, and the femur was loose from its head

It should be easy to distinguish osteomyelitis from rheumatic fever, since, at the onset, only one point is involved, and that near a joint and not in it The face is flushed the tongue dry, the temperature high, and there is usually delirium at night , whereas, in rheumatic fever more than one joint is painful, the face is pale, the skin moist, the tongue large and flabby, the temperature rarely above 103° F , and delirium very unusual.

As illustrating the pace at which osteomyelitis progresses, I will quote two cases

Many years ago at the Royal Sussex County Hospital a child of 10, who was convalescing from a minor ailment, developed a temperature of 104° F on my visiting day, and complained of pain in his ankle I found a very tender spot over the lower epiphysis of his right fibula Diagnosing acute osteomyelitis, I told the house physician to *send for a surgeon at once* The *house physician, it being* his afternoon off, neglected to send for the surgeon until next morning By that time the whole of the lower half of the fibula was inflamed and it ultimately came away as sequestra, the child being in the hospital for about four months

The other case was that of a boy of 15 at school, who complained of feeling ill after lunch one day His temperature was found to be 105° F He was put to bed, a provisional diagnosis of influenza having been made His temperature at 6 P M was still 105°, and I was asked to see him He had no headache, but he looked very *poisoned, his pulse rate was 120* I found a small red swelling on the inner side of the left os calcis which was very tender on pressure, and decided that it was a case of *acute osteomyelitis of the os calcis* I had him moved to a nursing home at once, and Mr G W Beresford operated He found already a little pus and some bare bone, though *only six hours after the onset* He trephined a piece about the size of a thimble out of the os calcis The next day the temperature only went up to 102°, on the second day to 100 2°, and by the third day it was normal, and never rose above that again The wound was completely healed in five weeks, and the boy was able to walk about

Contrast this second case with that of a boy sent into the Brighton Infirmary as an acute rheumatism on the sixth day after he had begun complaining of pain in the right heel Dr S J Firth then rightly diagnosed acute osteomyelitis of the os calcis, and *the bone was cut down on and drained Unfortu*nately, with the six days' delay, a septicæmia affecting the bones had started An acute osteomyelitis of the right ulna developed, and some days later the left iliac bone was also attacked The ulna and the ilium were, of course, treated surgically, but the boy was desperately ill, and was only able to leave his bed after nine months He will be a permanent cripple with a deformed os calcis, an ankylosed hip joint, and an irregular newly formed ulna

It is really quite as important to operate at once on acute osteomyelitis as on a perforated appendix

LEPTOSPIRAL JAUNDICE
OCCURRING NATURALLY IN A GUINEA-PIG

BY NEIL MASON, M.B Liverp , D P H
GARRETT RESEARCH FELLOW IN BACTERIOLOGY, UNIVERSITY OF LIVERPOOL

ON Dec 2nd, 1936, a batch of twelve guinea pigs arrived at the City Laboratories, Liverpool, from a dealer The following *morning* one was found dead showing yellow staining of the ears and feet A post mortem examination revealed jaundice and petechial hæmorrhages into the skin, hæmorrhages into muscle and fasciæ, and " butterfly " hæmorrhages in the lungs Active leptospiræ were demonstrated by dark ground illumination in tissue emulsions made from the liver and kidneys

A guinea pig from stock was inoculated intraperitoneally with 1 c cm of liver emulsion *This animal* developed jaundice in five days and died in six, with an exactly similar post mortem picture to that of the first guinea pig. Leptospira morphologically similar to *Leptospira icterohæmorrhagiæ* were isolated in pure culture from the heart blood of both animals and were serologically identical with *L icterohæmorrhagiæ*.

Source of the Infection.—In reply to questions the dealer stated that there had been no case of jaundice amongst his staff or dogs that the food and water supply of the guinea pigs were protected against contamination by rats but that about ten days before the animals were sent to Liverpool rats had broken in and killed two or three guinea pigs. The infection was therefore most probably derived from a rat at the dealer's but there were no signs of injury to the animal, and there is insufficient evidence to decide whether it was acquired from a rat-bite or through contact with infected rats excreta.

Comment.—In the study of leptospiral infections guinea pig inoculation plays a very important part. The results of inoculation of *L icterohæmorrhagiæ* have not produced entirely uniform results. Taylor and Goyle (1931) failed to infect several guinea pigs with blood and urine from undoubted cases of Weil's disease. I have had experience of five cases where inoculation of emulsions of rat kidney in which active leptospiræ were seen by dark field examination failed to produce fatal infection in guinea pigs. When these animals were killed later their sera were found to agglutinate *L icterohæmorrhagiæ* in dilutions varying from 1/30 to 1/300. These failures may have been due to low virulence of the strains but they may also have been affected by the immunity of the guinea pigs which might conceivably have resulted from naturally acquired infections. Schüffner (1928) mentions the possibility of the spread of leptospirosis in guinea pig stock by unknown means. I have been unable to find any record of a natural infection in guinea pigs and the importance of recognising that it does occur has seemed to warrant that this case should be placed on record.

I desire to thank Prof H D Wright for the facilities and help given.

MEDICAL SOCIETIES

SOCIETY OF MEDICAL OFFICERS OF HEALTH

AT a meeting of the Fever and School Medical Groups of this society when Dr H S BANKS vice-president of the fever group took the chair a *discussion on*

The Control of Whooping cough

was opened by Dr A B DONALD. He first summarised the reasons for believing that whooping cough was due to *B pertussis* the bacillus he said was serologically one specific type and while almost *constantly present in the acute stages of the illness* was absent in other illnesses and in health. Except in very few cases, mostly very young infants specific antibodies to the bacillus developed in the blood in the later stages of infection. The period of infectivity coincided with the period of expectoration of the bacillus as found by the cough plate method.

Pure cultures injected intratracheally into apes produced an illness similar to pertussis. Furthermore, when pure cultures of *B pertussis* had been instilled into the nasal cavities of 4 volunteers 2 developed typical whooping cough while the other 2 who had been protected with Sauer's vaccine did not. On the other hand Stocks had shown that the epidemiology of the disease was somewhat similar to that of measles; the infectiousness, the solid immunity the interstitial pneumonia the demonstration of inclusion bodies in penumonic lesions and degenerative lesions of nerve ganglia were stated to be indications of a virus infection. But hospital experience showed that pertussis seldom gave rise to cross infection in a ward as measles did; and if the organism was a secondary invader why was it so constantly present in the early stages?

In the belief then that the infection was solely due to *B pertussis* the speaker discussed the methods in use for the diagnosis of pertussis and the results obtained at the North Western Hospital. Dr Donald had been using three specific diagnostic tests. The first of these the cough plate was the principal and only certain method of early diagnosis. In this the patient coughed on to a Petri dish containing the Bordet-Gengou medium of *potato extract glycerol*, agar and defibrinated blood the latter being present in a proportion of 50 per cent as lower concentrations were not reliable. The plate was held about 4 in from the mouth and exposed to a number of barks. The colonies were subcultured and then typically looked like a streak of aluminium paint. The organisms were emulsified for agglutination tests and also stained by Gram's method showing the short cocco bacilli in clumps like a thumb print. Dr Donald showed by slides that a fair number of positive plates were obtained in the fourth week of infection. Negative dismissal plates had been used as a basis for the early *transfer of children to the* convalescent hospital.

The complement fixation test had been done on the serum of every patient admitted to the whooping cough wards and had been a very useful method of diagnosis in late cases. It served to indicate the approximate duration of the disease, being negative during the first two weeks doubtful or weakly positive in the third and usually positive from the fourth week onwards with a rising titre to the seventh or tenth. The antibody response was usually delayed in patients who developed secondary bronchopneumonia but even they eventually gave a positive complement *fixation test. As the test was found* to be negative in 8 convalescent cases by the thirteenth week on average it was thought to be probably only positive during active infection. In 1934 Bernholdt Thomsen had stated that the specific antibodies only showed that the subject had recently been under the stimulus of the specific antigen and not that he had recently suffered from infection. This had not been borne out by Dr Donald's experience. The test appeared therefore to be specific for active whooping cough with a few exceptions. About 30 to 40 sera giving strongly positive complement fixation tests were tested for agglutinins but all except one were completely negative although different strains and various methods of incubation were tried.

Skin tests performed by intracutaneous injection of a killed vaccine containing a thousand million organisms per cubic centimetre had confirmed the opinion that skin tests done with the whole organism were of little value No evidence of an initial leucopenia had been found from the blood counts carried out as a routine on admission, but a leucocytosis with relative lymphocytosis had been found in practically every uncomplicated case The return to normal in cases of whooping cough was very slow In July, 1936, Bell and Gold had shown that in contrast to other infectious diseases, the sedimentation rate was retarded during the acute stages of whooping cough Dr Donald had confirmed this in 46 cases and considered the test was of value as an early diagnostic sign.

Dr W GUNN said that while bacteriologists were agreed that the Bordet Gengou bacillus was invariably associated with whooping cough they were not certain about the possibility of an associated virus Some American workers had injected filtered material into the trachea of apes and produced a catarrh which might correspond to the initial catarrh of pertussis The application of Dr Donald's work lay in assisting early diagnosis The policy of the London County Council schools was no longer to put schools or dormitories into isolated quarantine but to put the children under observation and remove them as soon as symptoms appeared This policy was successful in day schools but might have to be revised for measles and pertussis in the resident schools Children with whooping cough might be infectious for from one to three weeks before they were excluded, by which time the disease had a firm hold on the school He had known the infection to persist for months or even a year, not in epidemic form but in three or four cases every few weeks He had recently been trying the cough plate method. His difficulties differed from those of the bacteriologist the schools were in country districts, the plates had to be kept cold before exposure and were liable to break in transport A package was being devised for taking Petri dishes so that they could be sent by post in this country as they were in Denmark. Special staff was required to handle the plates and to collect the product of the coughs on them He thought that soon the plate method might well be used extensively in schools Positive plates had been obtained in about one third of the cases at the fourth to sixth weeks and had been observed up to the twelfth, but that did not necessarily mean that the children were still infectious

Dr A R THOMPSON described his experiences with the skin test Vaccines of pertussis would only cause pustules which were of no significance, he had consequently tried the experiment of using non pathogenic bacteria of the same size, for this he had used *B prodigiosus* and had obtained much better reactions He had also tried endotoxin solutions In his experience the attack rate was not high and the infection did not go round wards, he thought that where that happened the possibility of an undetected case keeping up the infection should be considered The collecting of material on plates was so difficult that he had tried inducing coughs in order to obtain an early diagnosis

Dr T P PUDDICOMBE wondered what percentage of whooping cough cases never whooped, practitioners generally insisted on waiting for the whoop's appearance before making the diagnosis In schools the patients were still isolated for six weeks after the onset of cough and contacts for three The child who was out and about often progressed well while the child who was carefully treated developed broncho pneumonia

Dr R CRUICKSHANK said that the bacteriological work of pertussis was not easy, much depended on the technique of producing a really good medium, for instance, and blood was difficult to acquire, the actual picking off of colonies needed long experience He considered that to say that a child with a positive dismissal plate was not infectious was to deny all that we knew of carriers, the carrier need not transmit the illness but must be regarded as a potential source of infection

Dr A TOPPING pointed out that there were avirulent diphtheria bacilli, the presence of *B pertussis* did not therefore necessarily imply infectivity Hospital treatment of pertussis could not be as extensive as they wished while public opinion thought cases had to be kept in so long

Dr BANKS said he was glad that the difficulties of the cough plate method had been stressed, he had found it unreliable except in the hands of a few experts He had only obtained positive plates in 20 per cent of cases, although he had the help of a good laboratory He would like the bacteriologist to tell other workers which details were of vital importance in the technique, even after that, special experience would, he believed, be necessary for the work. He asked whether the time had not come to repeat Madsen and Sauer's work on preventive inoculation, resident schools were the ideal place for the experiment At the Park Hospital oxygen carbon dioxide inhalation had been tried as a form of treatment Dr Muir had tried oxygen with 7 per cent CO_2 to produce deep breathing for ten minutes three times a day, thinking that it might help to clear away mucus from the bronchi and to prevent broncho pneumonia He had been unable to draw any definite conclusion from those results, but the inhalations were apparently of real value for whooping cough cases which failed to resolve If the method prevented bronchiectasis as a sequela it was doing something The carbon dioxide caused spasm and cough and could be used to induce a cough, say, before a meal

MEDICO-LEGAL SOCIETY

AT a meeting of this society held on Feb 25th, Mr C AINSWORTH MITCHELL, D Sc, the president, being in the chair, Mr PAUL C DAVIE read a paper on

Silicosis An Administrative Experiment

He put forward the suggestion that the administrative structure of certain schemes made under the Workmen's Compensation (Silicosis) Acts might with advantage be extended After giving a brief description of the Acts and the schemes made under them, the speaker confined his attention to two schemes, which he aptly termed the "fully developed" schemes, for the refractories industry and the sandstone industry Under each of these schemes the whole industry was formed into a company which was responsible for meeting all claims for compensation in respect of workmen certified to be suffering from silicosis or silicosis with tuberculosis, or to have died from one of these diseases Claims were made against the whole industry, represented by the company, and not against an individual employer, and were met out of a fund subscribed by the industry Medical certificates were given only by a medical board, appointed by the Secretary of State, and claims were decided by an unpaid joint committee consisting of three employers' and three workers representatives, with an independent chair man By these means the usual court procedure for settling claims was entirely eliminated and so far as he knew this administrative structure was without precedent. A remarkable feature of these two schemes was the smoothness with which they had worked during 12 years in the case of the refractories industries scheme and 8 years in the case of the sandstone industry scheme The formation of such a scheme depended on the agreement of the industry concerned and its smooth working was possible only with the active coöperation of its members Although one industry for which such a scheme had been proposed had turned it down it seemed possible by suitable grouping to extend the principle of the fully developed scheme to industries in which at present a partially developed scheme applied The speaker emphasised the important effect such a scheme must have in urging an industry to adopt and improve all possible means of prevention The speaker discussed the finality of the certificate of the medical board, and commented on the possibilities for research into the course of the disease from the records and material collected He suggested that the system of medical boards might be extended to cover other diseases

In the course of discussion Dr S W FISHER of the Mines Department referred to the unequal distribution of silicosis amongst workers in coal mines in this country and suggested that this might be an obstacle to the adoption of a fully developed scheme for the coal mining industry —Dr G SLOT referred to the organisation for silicosis in South Africa, and Mr DAVIE in his reply said that in this country we owe much to the example and published experience of the South Africans and to the International Conference on Silicosis held in Johannesburg in 1930

BRITISH PSYCHOLOGICAL SOCIETY

MEDICAL AND EDUCATION SECTIONS

AT a joint meeting of these sections held on Feb 24th the chair was taken by Dr H CRICHTON MILLER, president of the medical section A discussion on

Sex Education

was introduced by Dr SUSAN ISAACS She emphasised that sex education was by no means the same thing as sex instruction and that the problem was not simply one of ignorance or knowledge of a series of external facts The child's feelings, wishes relations to people and aims in life were involved in sex education at all ages The object of sex education was to foster right attitudes wisdom and happiness Moreover it went on all through life whether conscious or not The question was not whether such education should be given but how it was to be given The child brought deep emotions to the problem The relation between the two parents was of overwhelming importance to him but he was concerned not with the actual act but with whether what father and mother did together was good or bad in the sense of his own feelings and fantasies whether it was life giving loving and creating or destroying and hating His impulses and his experiences prepared him for knowledge of the genital act The union and satisfaction at the breast prepared him for genital union and satisfaction To put pegs into holes was a profound natural impulse of little children Apparent ignorance was not a result of lack of experience and opportunity but of profound anxiety Many motives entered into that façade of ignorance the boy's love of his mother and fear of his father both played their part Little children often fantasied that babies were made from food or fæces and their feeling about it was of great importance This linked with the breast experience Penis-envy in the little girl was a factor but was not a simple thing being linked with anxiety about the feminine function and fear of its frustration Equally important was the child's actual experience of the day to-day ordinary relations of his parents Often children who knew quite well what happened in sexual intercourse but had good reason to believe it did harm showed exaggerated infantile theories, especially sadistic ones. The parents feelings in teaching the child were obviously very important: shame solemnity reticence or a deep belief in the goodness of sexuality The child's understanding worked less easily here than anywhere because of conflict and emotion

To the child under 9 or 10 with incipient knowledge and conflicts information was worth giving for the sake of indicating to the child the parent's attitude in the matter Lying and evasion convinced the child of the badness of sexual relations and the badness of wanting to know about them Association with animals was good because the problem was one degree removed and thus less acute Another part of sex instruction was the establishment of privacy without a sense of shame. Questions should be answered when asked the natural period for them was 3 4 or 5 Later the child often did not want to know about these things and there should be no forcing in the matter The emotional content of the questions should be noted If the child went on asking in a compulsive way the question had not been adequately answered. Questions could not be answered once for all because the problem was an emotional and not an intellectual one and would inevitably recur There was little trouble in telling the mother's part the difficulty was to explain the father's part, which was the core of the child's difficulties Answering questions helped even though he completely forgot the answer because it showed that there was no objection to knowledge because it relieved his anxieties about the badness of sexual intercourse because the sharing was an act of love and because it built up his faith in his own future and gave him permission to grow A small child of two had been found standing in front of a mirror saying reflectively Rather like a man Telling about the father's part helped to encourage that attitude of hopefulness Sometimes it was best if the father explained his own part The little girl was encouraged by being told that she had an internal organ corresponding to the visible male organ For small children the parent was the best informant in later years other people might be better The child should not be warned not to speak to other children about these things Children should be allowed a sense of humour No answer solved all the child's problems, and the difficulty was bound up with the child's total relationships Nor was the problem solved by little text books and a few lessons though these were helpful when they rested on continual loving helpfulness on the part of the parents

Mr LYN HARRIS spoke of the necessity of close relationship between home and school so that the attitude of each might be appreciated in the other There should be a direct continuation of experience and no divergence The school approach to all questions of knowledge and behaviour was most important There should be no sense of taboo and no sense of a conventional conclusion, which had to be reached regardless of the right result for a particular child The school must have the right attitude to all bodily functions Coeducation was a great help because the life could be a natural one and an extension of family life *Coeducation must not be* forced, but differences should not be smoothed over but taken naturally The menstrual period should be carefully explained to both sexes in relation to physical exertion Staffing should be regarded as the right admixture of adults in a non adult community, and the adults should be living a full harmonious life Married men and women should be among them An atmosphere in the school of a really happy married life was of the utmost importance *Class instruction* was to be avoided, but in groups under the age of 7 questions might arise which could suitably be discussed for example, a litter of sandy kittens born to a tabby cat might lead to a natural and useful discussion Problems cropped up during nature study and the whole thing could be dealt with quite naturally In the teaching of biology sex teaching should be implicit rather than explicit Problems involving an emotional attitude should be dealt with personally as far as possible The library should be well stocked. The whole thing was to treat the matter just like any other approach to knowledge, so that the subject was not set apart, or emphasised or smoothed over
